ANTISENSE VIRUSES AND ANTISENSE-RIBOZYME VIRUSES

Field of the Invention

This invention relates generally to artificial antisense viruses (ASV) and antisense-ribozyme viruses (ARV), and to use such viruses to inhibit the replication of natural viruses.

Background of the Invention

Antisense technologies have been employed primarily to block gene expression. During the process of gene expression, the information encoded in a gene (DNA) is first transcribed into a messenger RNA (mRNA) that is in turn translated into a protein. The original idea behind antisense technology was to create a piece of polynucleotide (RNA or DNA) with a base sequence complementary to that of a particular messenger RNA. This antisense RNA would bind to the mRNA, preventing it from being translated into protein as shown below:

APPROACHES BY OTHER RESEARCHERS RELATED TO ANTISENSE STRATEGY

A. Antisense Expression Constructs

Genes are composed of two strands of DNA, only one of which is normally transcribed into mRNA. If the protein-coding portion of the gene is flipped over, the gene's regulatory sequence will cause the other - or "wrong" - strand to be transcribed, allowing a cell to produce antisense RNA. The antisense RNA produced by the flipped gene will bind and inactivate the RNA produced by the normal gene.

Izant JG & Weintraub H. Cell 36:1007-15 (1984) showed that the synthesis of the enzyme thymidine kinase (TK) could be blocked in mouse cells if a flipped version of the thymidine kinase gene was introduced into the cells along with the normal gene.

Two independent groups (Sheehy RE et al. Proc Natl Acad Sci USA 85:8805, 1988; Smith CJS et al. Nature 334:724, 1988; Smith CJS et al. Plant Mol Biol 14:369, 1990) created mush-resistant tomatoes by genetically engineering the plant to contain a flipped version of the gene for polygalacturonase, an enzyme that breaks down plant cell walls. As a result production of the enzyme was reduced up to 99% without directly disrupting the expression of other genes. Otherwise, the tomato plants appeared normal (Moffat AS. Science 253:510, 1991).

Oeller et al, Science 254:437 (1991) describe reversible inhibition of tomato fruit senescence by antisense RNA. The authors chose one of the other targets to control tomato fruit ripening. They introduced into tomato plants an antisense RNA expression vector to 1-aminocyclopropane-1-carboxylate (ACC) synthase, the rate-limiting enzyme in the biosynthetic pathway of ethylene which controls fruit ripening. The expression of the antisense RNA in the transgenic tomato plants inhibited tomato ripening and the biochemical changes associated with it, such as softening, color and aroma development. Administration of exogenous ethylene or propylene reversed the inhibitory effect. The authors noted that expression of antisense RNA to ACC synthase may

ameliorate losses due to over-ripening of fruits and vegetables during transp rtation or because of lack of r frigeration.

Day AG et al. Proc Natl Acad Sci USA 88:6721-5, 1991, report the application of antisense RNA technology, in plants, to achieve resistance to infection by a geminivirus. The authors constructed transgenic tobacco plants carrying a genetic cassette including an antisense DNA sequence of the virally encoded AL1 gene of the geminivirus tomato golden mosaic virus (TGMV). AL1 encodes a protein absolutely required for TGMV DNA replication. After infection of plants with TGMV, the frequency of symptom development was very significantly reduced in a number of antisense lines, and no DNA replication was seen in five of the six antisense lines studied, in contrast to controls.

Han L, Yun JS & Wagner TE. Proc Natl Acad Sci USA 88:4313-4317 1991, genetically engineered mice to express an antisense RNA to the Moloney murine leukemia virus (M-MμlV) proviral packaging sequences, which are needed to make infectious particles of the leukemia-causing virus. When these transgenic mice were infected with M-MuLV on the day of birth, none developed any symptoms of leukemia, although 31% of the control animals did.

The Wagner group's results caused molecular geneticist John Rossi of the city of Hope Medical Center in Duarte, California, to declare that "antisense is going to be a powerful antiretroviral tool." It might be possible, Wagner suggested, to genetically engineer lymphocytes, one of the major cell types infected by the AIDs virus, with antisense constructs that prevent the virus from replicating (Moffat AS. Science 253:510, 1991).

B. Synthetic Antisense RNAs or DNAs

Melton's group (Melton DA. Proc Natl Acad Sci USA 82:144, 1985; Rebagliati MR & Melton DA. Cell 48:614, 1987) showed that synthesis of

specific proteins could be prevented in frog eggs simply by injecting them with synthetic antisense RNAs.

Calabretta's group (Szczylik C et al. Science 253:562-65, 1991) made a short, single-stranded antisense DNA, just 18 nucleotides long, that specifically recognizes the junction of the ABL hybrid gene resulted by "philadelphia chromosome translocation". The antisense construct stops the growth of the cancer cells but not that of the normal cells from which the cancer cells were derived.

ANTISENSE STRATEGY RELATING TO HIV-1

A. Antisense Oligonucleotides

Vickers, et al, Nucleic Acids Res., 25 19(12):3359-68 (1991) describe inhibition of HIV-LTR gene expression by oligonucleotides targeted to the TAR elements. A series of phosphodiester and phosphothioate antisense oligonucleotides were constructed which specifically bind to the HIV TAR element. The reason for using the phosphothioate analogues was based on the fact that these analogues are more resistant to degradation by DNase activities, enabling higher oligonucleotide concentration inside the cells.

Renneisen, et al, J. Biol. chem., 25 265(27):16337-42 (1990), describe inhibition of expression of human immunodeficiency virus-1 in vitro by antibody-targeted liposome containing antisense RNA to the env region. Treatment of HIV-1IIIB infected H9 cells with in vitro synthesized viral env region antisense RNA encapsulated in liposomes targeted by antibodies specific for the T-cell receptor molecule CD3 almost completely inhibited HIV-1 production. The viral env segment covered a part of exon II of HIV-1 tat gene. No anti-HIV activity could be detected with similarly targeted liposome-encapsulated sense env RNA or with pol RNA synthesized in either the sense or antisense orientations, or with env region antisense RNA free in solution, or

encapsulated in liposomes in the absence of the targeting antibody. A semiquantitative evaluation revealed that 4000-7000 RNA molecules became cell-bound in targeted liposomes; the half-life of the intracellularly present hybridizable antisense env RNA was approximately 12 hours. Western blots showed that antisense env RNA suppressed tat gene expression by approximately 90% and gp160 production by 100%. These data were confirmed by immunoprecipitation studies. Northern blots (using an env probe) demonstrated the existence of all major HIV RNA species (9.3-, 4.3-, and 2.0-kb mRNA) in HIV-infected cells treated with antisense env RNA although at a reduced level. It was concluded that the antisense env RNA inhibited viral protein production at the translational level.

B. Antisense Expressing Constructs

Rhodes et al, J. Gen. Virol., 71(pt9):1965-74 (1990), describe inhibition of human immunodeficiency virus replication in cell culture by endogenously synthesized antisense RNA. Six regions from HIV-1IIIB were inserted into retroviral gene expressing vector in antisense orientation. Two of these expressed antisense RNAs were found to reduce significantly the replication of HIV-1IIIB in cell culture. The inhibitory antisense RNAs contain sequences complementary to the AUG initiation codon of the tat gene. Inhibition was substantial (over 70%) but transient. At least part of the inhibitory effect is at the posttranscriptional level.

Rhodes et al, AIDS, 5(2):145-51 (1991), describe inhibition of heterologous strains of HIV by antisense RNA. The longer (600 bases) of the two inhibitory antisense RNAs inhibits replication of HIV strains RF, MN and SF2 to at least as great an extent as it does the homologous strain IIIB. The shorter one (71 bases) does not inhibit the replication of the heterologous strains. The level of inhibition of HIV-1IIIB replication varied according to the cell line in which it was expressed, but in all cases was significant.

Rittner et al, Nucleic Acids Res., 19(7):1421-6 (1991) disclose

identification and analysis of antisens RNA targ t regi ns of the human immun deficiency virus type 1. Antis nse RNA, transcribed intracellularly from constitutive expression cassettes, inhibits the replication of HIV-1 as demonstrated by a quantitative microinjection assay in human SW480 cells. Infectious proviral HIV-1 DNA was co-microinjected together with a fivefold molar excess of plasmid expressing antisense RNA complementary to a set of ten different HIV-1 target regions. The most inhibitory antisense RNA expression plasmid were targeted against a 1 kb region with the gag open reading frame and against a 562 base region containing the coding sequences for the regulatory viral proteins tat and rev.

Objects of the Invention

It is an object of the invention to provide novel compounds and methods of treating and preventing viral infections including HIV infections.

It is an object of the invention to provide therapeutic agents for the treatment and prevention of AIDS having:

(1) the ability to target HIV;
(2) the power to inactivate (disable or eliminate) HIV;
(3) the specificity to act only on HIV;
(4) the potential to protect the cells against HIV;
(5) a long in vivo life.

It is an object of the invention to provide a method of producing antisense viruses.

It is an object of the invention to to provide a method of producing antisense-ribozyme viruses.

Summary of the Invention

The present invention provides an antisense virus comprising a viral coat sufficiently duplicative of a naturally occurring virus viral coat to allow the infectivity of the naturally occurring virus, and nucleic acid including an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for the naturally occurring virus to replicate. The antisense fragment encodes antisense RNA capable of binding and inactivating mRNA encoded by the gene encoding a transactivating protein.

The invention further provides a process for the production of an antisense virus. The process comprises the steps of a) growing under suitable nutrient conditions procaryotic or eucaryotic host cells transfected in a manner allowing expression of said antisense virus, with:

i) a first DNA sequence including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for the naturally occurring virus to replicate, and

ii) a second DNA sequence encoding the transactivating protein, and b) isolating the antisense virus.

Also comprehended by the invention is a method of treating or preventing a viral infection comprising administering to an infected animal a therapeutically effective amount of an antisense virus.

Also provided is an antisense-ribozyme virus comprising a viral coat sufficiently duplicative of a naturally occurring virus viral coat to allow the infectivity of the naturally occurring virus, and nucleic acid including an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for the naturally occurring virus to replicate. The antisense fragment encodes antisense RNA capable of binding and inactivating mRNA encoded by the gene encoding a transactivating protein. The antisense fragment also encodes at least

ne rib zyme capable of cleaving the mRNA.

The invention further provides a process for the production of an antisense ribozyme virus. The steps include a) growing under suitable nutrient conditions procaryotic or eucaryotic host cells transfected in a manner allowing expression of the antisense ribozyme virus, with:

i) a first DNA sequence including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for the naturally occurring virus to replicate. The antisense fragment encodes antisense RNA capable of binding mRNA encoded by the gene encoding a transactivating protein. The antisense fragment also encodes at least one ribozyme capable of cleaving the mRNA, and

ii) a second DNA sequence encoding the transactivating protein, and b) isolating the antisense ribozyme virus.

Also included in the invention is a method of treating or preventing a viral infection comprising administering to an infected animal a therapeutically effective amount of an antisense-ribozyme virus.

The invention also provides a method of connecting a first DNA segment to a second DNA segment, when the first DNA segment and the second DNA segment are separated by a length of DNA or located on different molecules. The method comprises carrying out polymerase chain reaction using the DNA segments as templates, and using a primer A complementary to the 5' end of the first DNA segment, a primer B complementary to the 3' end of the second DNA segment, and a bridging primer comprising DNA complementary to the 3' end of the first DNA segment as its 5' half, and DNA complementary to the 5' end of the second DNA segment as its 3' half, as primers.

Brief Description of the Drawings

FIGURE 1 shows pX (short for pHXB2gptX). Three arrows point to three EcoNI sites. When sites #2 and #3 are eliminated, pX becomes pXE.

FIGURE 2 shows the genomic structure of HIV-I. Each of the nine known genes of HIV-1 are shown, and their recognized primary functions summarized. The 5' and 3' long terminal repeats (LTRs) containing regulatory sequences recognized by various host transcription factors are also depicted, and the positions of the Tat and Rev RNA response elements (TAR (transactivation response) element and Rev response element) are indicated.

FIGURE 3 shows a schematic diagram of the HIV-1 Virion. Each of the virion proteins making up the envelope ($gp120^{env}$ and $gp41^{env}$) and nucleocapsid ($p24^{gag}$, $p17^{gag}$, $p9^{gag}$, and $p7^{gag}$ is identified. In addition, the diploid RNA genome is shown associated with reverse transcriptase, an RNA-dependent DNA polymerase.

FIGURE 7b is a diagram of SFneo-tat(-).

Detailed Description of the Invention

The subject invention relates to antisense viruses (ASV) and antisense ribozyme viruses, their synthesis, and their use in treating and preventing viral infections.

Antisense viruses are artificial viruses carrying antisense nucleotide sequences to their natural counterparts. Antisense RNAs expressed by the antisense viruses bind to the mRNAs expressed by the naturally occurring viruses and prevent the mRNAs from being translated into proteins, thereby preventing the naturally occurring virus from replicating. The antisense viruses maintain the infectivity of the naturally occurring viruses, allowing antisense RNAs to reach the mRNAs of the natural viruses. Antisense virus strategy provides a new therapy for viral, including retroviral diseases.

The antisense virus of the invention comprises the viral coat (i.e., the envelope and optionally the capsid in the case of enveloped viruses, and the capsid in the case of viruses without an external envelope) sufficiently duplicative of a naturally occurring viral coat to give the antisense virus the infectivity of the naturally occurring virus, and nucleic acid including an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate. The antisense fragment encodes antisense RNA which is capable of binding and inactivating mRNA encoded by the gene encoding a transactivating protein. Typically, the viral coat of the antisense virus is identical to the corresponding naturally occurring virus. The nucleic acid of the antisense virus typically contains all the structural genes of the naturally occurring virus. Further, nucleic acid typically includes all of the regulatory genes of the naturally occurring virus except the gene encoding the transactivating protein. Advantageously, the nucleic acid of the antisense virus is the same as the nucleic acid of the corresponding virus with the exception of the antisense fragment (which replaces a section of a gene). Since the antisense virus does not contain a gene required for replication of the virus, the antisense virus is replication defective. The antisense fragment is part or all of the gene encoding the protein required for replication, turned antisense. The length of the antisense fragment must be sufficient to permit the antisense RNA transcribed from the antisense fragment to bind and inactivate the mRNA encoded by the gene encoding the required protein of the naturally

occurring virus, thus thwarting r plicati n of the naturally occurring virus. Thus, the antisense fragment is part or all f the target gene turned antisense. As used herein, the term "section of a gene" refers to part or all of the gene(s) encoding the transactivating protein(s) required for the naturally occurring virus to replicate.

The antisense virus of the subject application is made for use in treating or preventing disease caused by a wide variety of naturally occurring viruses. Antisense viruses is made to treat or prevent animal or plant viral infections. Further, antisense viruses are made to render inactive DNA as well as RNA viruses. Further, the antisense virus of the invention is used to treat or prevent infections caused by retroviruses.

Since the antisense virus of the subject invention is replication defective, a special host cell is required to produce the antisense virus in vitro. The antisense virus is replication defective since it does not contain a gene encoding a protein required for replication. In order for the host cell to be able to construct an antisense virus, it must contain a gene encoding the protein which the antisense virus requires. This protein must be a transactivating protein since it is supplied by a source other than the nucleic acid of the antisense virus. In order to avoid the antisense RNA encoded by the antisense fragment from binding the mRNA transfected from the complemental gene, the complemental gene sequence is typically "diversified" such that the antisense RNA will not bind the mRNA transcribed from the complemental gene. The amino acid sequence of the protein produced by the complemental gene, however, is the same as the corresponding protein of the naturally occurring virus.

In order to construct the cell line which produces the antisense virus, the complemental gene can be transfected into the host cell before, at the same time, or after transfection of the host cell with the gene encoding the antisense virus.

The subject invention also relates to antisense-ribozyme viruses (ARV) which are the same as antisense viruses except one or more ribozyme

catalyst sequenc s have been inc rporated into the antisense sequence(s). The antisense-ribozyme viruses are structured such that the binding of the antisense RNA to a particular mRNA will meet the requirements for the formation of specific structure enabling ribozymes to cleave the particular mRNA at predetermined positions. The ability of ribozymes to cleave RNA plus the binding specificity of antisense RNA give antisense-ribozyme viruses the ability to eliminate the natural viruses.

Antisense viruses and/or antisense-ribozyme viruses are often referred to collectively herein as "antisense/ribozyme viruses" or "ASV/ARV".

Although antisense viruses and/or antisense-ribozyme viruses to HIV-1, HIV-2 (human immunodeficiency viruses type 1 and 2) and SIV (simian immunodeficiency virus) are exemplified herein, the strategy is applicable to other viruses.

Definitions

ANTISENSE/RIBOZYME HIV-1 CLONES

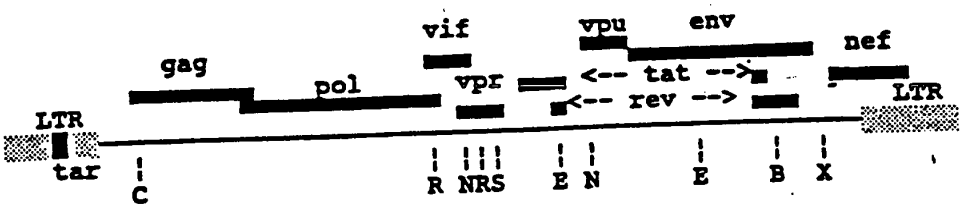

A. Full-Length Proviral Molecular Clones and Antisense/Ribozyme Proviral Molecular Clones:

pX: Short for pHXB2gptX. HXB2 is a functional HIV-1 molecular clone which has been widely employed in many kinds of experiments all over the world. The plasmid construct of pX is shown in Figure 1.

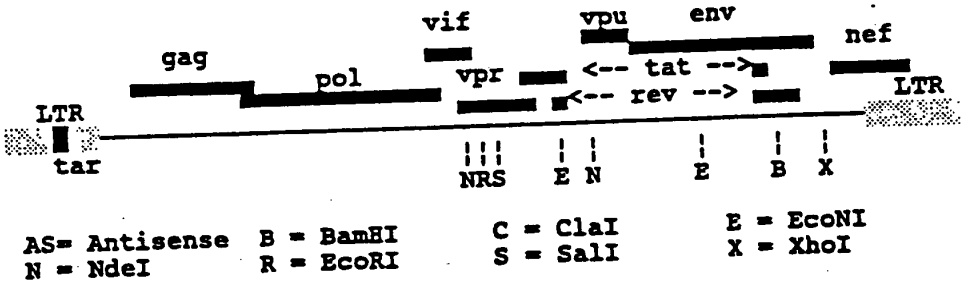

The genomic structure of HIV-1 is shown in Figure 2. A schematic diagram of the HIV-1 virion is shown in Figure 3.

The genetic organization of parental pX (HIV-1IIIB) is shown below. Only those restriction enzyme sites to be used during the construction

procedures are shown.

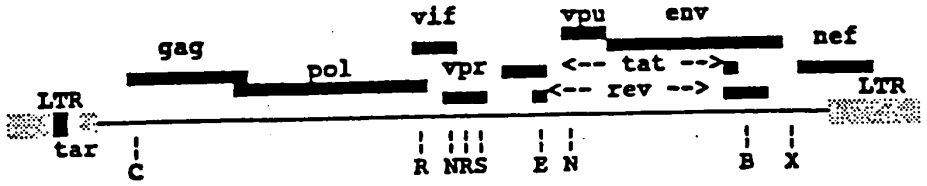

pNL: Short for pHIVNL4-3. An infectious recombinant HIV-1 clone that contains DNA from HIV isolates NY5 (5' half) and BRU (3' half). The site of recombination is the unique EcoRI site at nt 5743-5748. The vpr coding region of pNL is 18 amino acid residues longer than that of pX, due to a single "T" base deletion at nt 5770. The genetic organization of pNL is almost the same as pX, but the vpr is longer, and the ClaI site and the first EcoRI site are missing.

pXE: Modified from pX to facilitate the construction of antisense/ribozyme clones. A "T" to "G" point mutation has been introduced at nt 7633 in order to abolish the second EcoNI restriction site within the proviral sequence. The EcoNI site outside the proviral sequence has also been removed by polymerase fill-in and religation. pXE is considered the same as pX, but has only one EcoNI cleavage site at nt 5966 in the whole clone. The point-mutation introduced does not change the protein sequences.

Genetic organization of pXE is as follows (see also Figure 4). Note

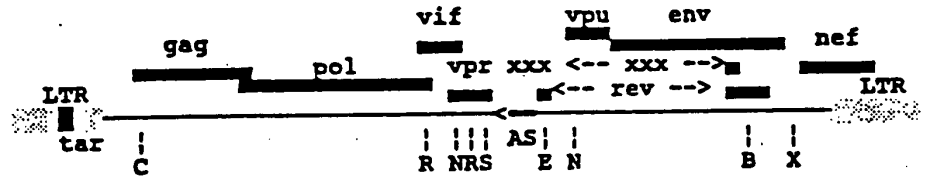

the second EcoNI site has been deleted. The deletion, however, did not change the genetic organization.

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

pXE-a: A DNA fragment of 171 base pairs, from nt 5795 to nt 5965, covering 45 amino acid codons of the N-terminus of the TAT protein, has been turned antisense. Consequently, the production of the whole TAT protein would be eliminated.

Genetic organization of antisense clone pXE-a is as follows (see also Figure 4). The sequence between SalI and EcoNI sites has been turned antisense. As a consequence of this inversion, the tat gene is destroyed and the whole clone becomes replication defective.

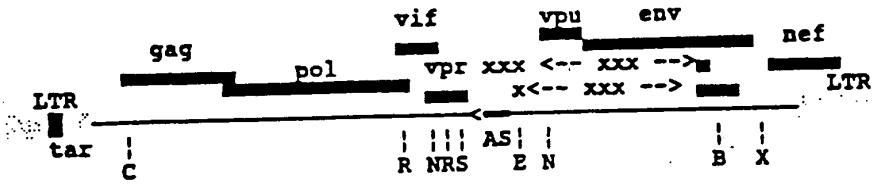

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

pXE-b: Same as pXE-a plus the nt 5970 "T" has been mutated to "G". As the consequence of this point-mutation, the initiation codon of rev is erased as is the whole REV protein.

Genetic organization of antisense clone pXE-b is as follows. The sequence between SalI and EcoNI sites has been turned antisense. Consequently, the tat gene is destroyed and the whole clone becomes

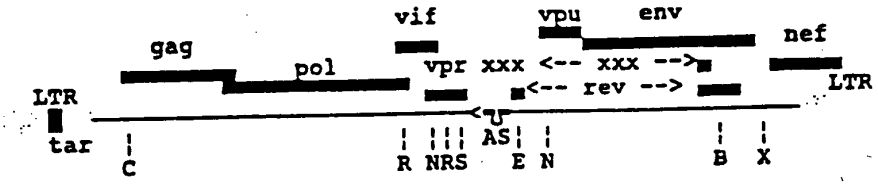

replication defective. Additionally, the initiation codon of rev gene has been mutated and the rev gene too is eliminated.

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

pXE-ar: A ribozyme catalytic domain has been incorporated into the antisense sequence of pXE-a, thus adding the RNA cleavage activity to the antisense clone.

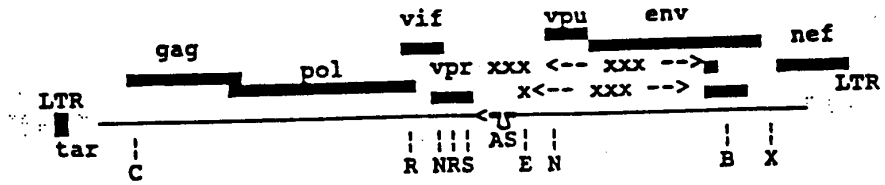

Genetic organization of antisense clone pXE-ar is similar to pXE-a (see Figure 4). Note the position of the ribozyme.

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

pXE-br: A ribozyme catalytic domain has been incorporated into the antisense sequence of pXE-b, thus adding the RNA cleavage activity to the antisense clone.

Genetic organization of antisense clone pXE-br is similar to pXE-b. Note the position of the ribozyme.

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

B. HIV-1 Subclones:

pX-N: Made from pX. An NdeI fragment of 1281 bps, from 5121 to 6402, has been removed from pX and religated. Included in the removed fragment, among other things, are the unique NcoI-5674, SalI-5785 and a EcoNI-5966. pX-N contains 2 other EcoNI sites, one at nt 7631 and the other outside the proviral sequences.

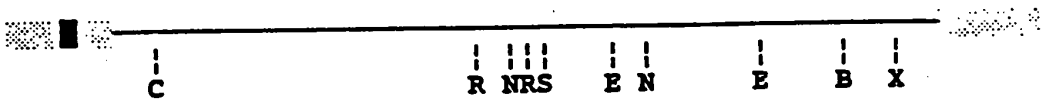

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

pX-N-E: Made from pX-N with the two EcoNI sites eliminated. The EcoNI-7631 has been point-mutated, and the outside EcoNI has been enzymatically erased.

pX-E2: The fragment of ClaI(829)-BamHI(8474) from pX has replaced the corresponding fragment of pX-N-E, thus putting back the 1281-bp NdeI fragment. Also put back are the EcoNI sites at nt 5966 and nt 7631.

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

pXE: The EcoNI site at nt 7631 has been point-mutated

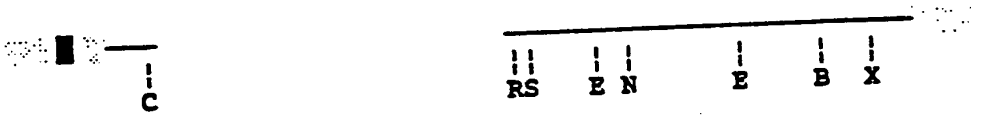

so the whole clone carries a unique EcoNI site at nt 5966. See also "Full-Length M lecular Clones or Mutants" above.

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

C: Gene-Expression Vector Clones:

pX-CS: A truncated HIV-1 clone made from pX and used as tat-expression vector. Removed from this clone are 4484 bps, from nt 836 to nt 5319 including most part of gag, all of pol and 5' half of vif open reading frames. The vpr, tat, rev, env, and nef genes and two LTRs are intact.

AS= Antisense B = BamHI C = ClaI E = EcoNI
N = NdeI R = EcoRI S = SalI X = XhoI

pX-CSneo: A 1146-bp neo(r) cassette containing an XhoI-SalI fragment has been inserted into the unique XhoI site in pX-CS. This clone has been endowed with neomycin resistance, but the insertion disrupts the nef gene.

pX-neo: Made from pX-CSneo. The SalI(5785)-XhoI(8896) (3111 bps) fragment, covering tat, rev and env coding regions, has been deleted from pX-CSneo. Essentially, pX-neo contains 2 HIV-1 LTRs with a neomycin resistant gene in between. This clone is used as neo(r)-only control.

SFneo: Retroviral gene expression vector which employs Spleen Focus Forming Virus (SFFV) LTR promotor to drive the

expressi n of the gene t be inserted int the unique EcoRI site. This clone is used als as ne (r)-only control. The plasmid structure is shown in Figure 5.

SFneo-t/r(+): Tat as well as rev reading frames in continuation has been inserted in right orientation into the EcoRI site of SFneo. This clone expresses sense tat and rev mRNA.

SFneo-t/r(-): Tat as well as rev reading frames in continuation has been inserted in wrong orientation into the EcoRI site of SFneo which employs Spleen Focus Forming Virus (SFFV) LTR promotor to drive the expression of the inserted gene. This clone expresses antisense tat and antisense rev mRNA.

SFneo-tat(+): Inserted in right orientation into SFneo vector at EcoRI site the chemically synthesized nucleotide sequence which is different from the natural nucleotide sequence. This clone expresses sense mRNA which is translated into TAT protein with amino acid sequence identical to that of the natural HIV-1.

SFneo-tat(-): Inserted in wrong orientation into SFneo vector at EcoRI site the chemically synthesized nucleotide sequence which is different from the natural nucleotide sequence. This clone expresses antisense RNA.

* * *

ANTISENSE VIRUSES

An antisense virus (ASV) is an artificial virus that expresses antisense RNA to one or more genes of its natural counterpart. An

antisense virus is generally replicati n defectiv , necessitating an antisense virus production system in order t pr duce large quantities of antisense viruses for therapeutic and preventive applications. The antisense virus production system comprises three components:

(1) an antisense proviral molecular clone;
(2) a complemental gene expression vector;
(3) an antisense virus producer cell line (host cells).

An antisense-ribozyme virus production system uses the same components (2) and (3) combined with an antisense-ribozyme proviral molecular clone (discussed below).

The function and establishment of each component of the antisense virus production system will be exemplified in detail for an antisense virus for HIV-1. Similar systems for other human viruses such as HIV-2 and SIV are easily developed by a person skilled in the art because of the similarity of genetic organizations between HIV-1, HIV-2 and SIV. The genetic organizations of HIV-1, HIV-2 and SIV are shown in Figure 6. Similar systems for other types of viruses can also be developed.

HIV-1 Antisense Proviral Clones

An HIV-1 antisense proviral molecular clone is made from a functional (infectious) HIV-1 molecular clone. It retains all of the natural HIV-1 structures and machinery except a part (or parts) of the genome has been turned antisense by sequence inversion. The antisense proviral clone is basically an intact molecular clone but the sequence inversion inactivates some functionally critical gene(s) and renders the whole clone replication-defective. However, the antisense proviral cl ne is constructed such that the function(s) of the inversion-inactivated gene(s) can be complemented by gene product(s) provided by another source or sources than the antisense clone itself. In other words, replication of the antisense clone depends on gene product(s) from source(s) other than the antisense clone itself.

In the presence of the gene product(s) provided by a "complemental gene expression vector" for functional complementation, the antisense proviral clone makes virus particles (antisense viruses) in the antisense virus producer cell line. The constant presence of gene product(s) is achieved by engineering the antisense virus producer cell line to express the protein(s) constitutively before, during or after the antisense proviral clone is transferred into the cells. With this antisense virus production system the antisense viruses are made in quantity in vitro.

The antisense virus is infectious and has the same "targeting" or "homing" specificity as the naturally occurring (wild type) virus. The antisense HIV-1 virus is able to attach to and enter CD4(+) cells, mediated by its normal envelope proteins (gp120 and gp41) just as the natural virus. Once inside the cells, the viral nucleocapsid reverse-transcribes its RNA genome into DNA, then integrates the viral DNA into the host genome, just as the natural virus does. But the antisense virus is non-replicative, hence non-pathogenic, in the absence of the gene product(s) that the antisense virus is missing. In the case where the antisense virus enters a healthy cell where no viral protein is being synthesized for functional complementation, the antisense virus will not replicate.

In the case where the antisense virus enters a cell which has already been infected by natural virus(es), the antisense virus will compete for survival (replication) with the natural virus(es) for the gene product(s) provided only by the latter. Once replicating, the antisense transcript (antisense RNA) will bind the natural transcript. The binding will shut off the natural viral protein synthesis; and vice versa. The consequence will be the inhibition, and eventually eradication, of the natural viruses and the antisense viruses.

If the antisense virus enters a cell which becomes infected later by a natural HIV-1 virus, the dormant antisense provirus (having integrated into the human genome) is re-activated by the gene product(s) encoded by the natural virus. Its transcription produces antisense RNA which shuts

off the natural virus.

If the cell never becomes infected by any natural HIV-1 virus, the antisense provirus will remain dormant and eventually be eliminated with the natural death of the cell. Potentially, the integrated antisense provirus, though unable to make virus without gene product(s) provided from other source(s), will divide with the cell, thus "arming" each daughter cell with one copy of the antisense proviral DNA.

Construction of Antisense HIV-1 Proviral Clones

The antisense HIV-1 proviral molecular clones are constructed with well-known functional (infectious) molecular clones, e.g., HIV-1IIIB and HIV-1NL4-3. The antisense RNA, once transcribed, will carry the same sequences (only some area in antisense orientation) as the wild type mRNA. The sense and antisense RNA sequences form complexes, a basic requisite for the antisense strategy to work.

In case an antisense clone made from an existing molecular clone does not work well with a particular patient's viruses because of sequence heterogeneity, an individualized antisense clone is made, using as a template the very virus strain infecting the particular patient. An antisense clone made in this way has exactly the same sequence (only in antisense orientation) as, and be able to form perfect duplexes with, that of the HIV-1 strain hosted by the patient (described further below).

Choosing Gene(s) for Inversion in HIV-1

An antisense clone is made by inverting part or all of one or mor genes of the naturally occurring virus to be neutralized. To be eligible for the inversion, the gene(s) must be indispensable for the replicati n of the virus, but must not be the structural genes. Structural genes,

i.e., in the case of HIV: gag, pol, and env, are necessary for the assembly of infectious virus particles. Infectious virus particles are employed as vehicles to deliver the antisense sequences effectively and specifically to the locations where the naturally infecting viruses reside. It is important for the antisense virus to preserve the natural devices and to retain the same "targeting" or "homing" function as that of the naturally occurring virus.

The rev gene encodes a 19-kd phosphoprotein which is essential for the replication of HIV-1. The Rev protein appears to exert its regulatory activity at a post-transcriptional level by activating the cytoplasmic expression of the unspliced and singly spliced forms of HIV-1 RNA that encode the products of the gag, pol, and env genes. In the absence of Rev, these incompletely spliced viral mRNAs remain sequestered in the nucleus, where they are either degraded or completely spliced. Apparently, Rev positively regulates the formation of virus particles. Since the rev gene overlaps with tat, it is impossible to turn rev antisense without also affecting tat. Thus, the complemental gene expression vector would have to express both rev and tat. Another consideration is that there is a splice junction site at the beginning of rev gene. If the splice junction sequence is turned over, the splicing may be lost, or placed at the wrong location, which would potentially impair the formation of infectious virus particles.

An antisense proviral clone can be made that knocks out the function of the rev gene while keeping the sequence basically unchanged. This goal is achieved by changing the "T" in rev initiation codon (position 5970) into a "G". The single base substitution will (1) abolish the rev gene product; (2) preserve the splice junction site; (3) preserve the unique EcoNI site which is critical in reconstructing antisense clone(s); and (4) create a new restriction enzyme site for AvrII, facilitating recombinant clone screening.

Advantageously, the tat gene is turned antisense. TAT corresponds to an 86-amino-acid nuclear protein that is essential for the replication

of HIV-1. TAT potently trans-activates the expr ssion of all viral genes. The TAT protein appears to contain three primary structural domains, including a proline-rich N-terminus, a cysteine-rich central portion, and a positively charged distal segment. The cysteine-rich domain (located between amino acids number 21-37 of the protein) probably mediates dimerization of the this trans-activator, whereas the positively charged distal segment is responsible for both RNA binding and nuclear-nucleolar localization. Thus far, no clear function has been ascribed to the proline-rich domain (located at the first 18 amino acids). TAT acts through an RNA stem-loop structure termed the "transactivation response element (TAR)", located at the beginning of all HIV-1 mRNAs. The preponderance of evidence suggests that it acts primarily at the level of transcription initiation, elongation, or both. TAT protein is trans-acting, therefore the TAT function abolished in the antisense clone can be easily compensated by introducing into the cultured cells a TAT-expressing cassette. The TAT protein expressed by this cassette will regulate the replication of antisense HIV-1 whose tat gene has been flipped over and rendered functionless.

Below is a description of a region of the tat gene being turned antisense.

Analyzing the Selected Area for Inversion in the TAT GENE

The original sequences between positions 5774 to 5986 in the HIV-1 molecular clone HXB2 are as follows [numbering according to GenBank, LOCUS HIVHXB2CG, 9718 bp, VRL 25-SEP-1987. DEFINITION: Human immunodeficiency virus type 1 (HXB2), complete genome; HIV1/HTLV-III/LAV reference genome. ACCESSION K03455]. Notice the coding sequences for the end part of vpr (which is different between clone pNL4-3 and HXB2), the beginning of tat-1 and rev-1, the two splice acceptor (sa) sites at positions 5776G/5777A and 5975G/5976G, the unique restriction enzyme sites of Sal-I and EcoNI (positions 5785 and 5966 respectively, both shown underlined. In the subject application, all restriction enzyme

sites are indicated by the first base of the enzymes' rec gnition sequences). EcoNI is unique in plasmid clone pXE but not pX, as d tailed later. The area written in bold-type [nucleotides (nt) 5795-5965] is to be turned antisense by sequence inversion.

Tryptophan	Trp	W
Tyrosine	Tyr	Y
Valine	Val	V

The inversion involves a total of 171 base pairs (bps). The sequence involvement for HIV1 was decided according to the following considerations. The sequence involvement for other viruses is also decided according to the following considerations.

First, the inversion advantageously should cover as much tat coding sequence as possible, especially the initiation codon (ATG) and the functionally important cysteine codons, in order for the antisense RNA expressed by the antisense viruses to bind as effectively to the natural viral tat mRNA as possible. The wide coverage also minimizes the possibility that the antisense proviral clones remain self-functioning.

Secondly, the inversion should cover as little other gene coding sequences and RNA processing signals as possible, especially the rev gene and splice junctions, in order for the antisense viruses to retain as much other gene functions as possible. The involvement with fewer genes minimizes the complexity for gene complementation by the complemental gene expression vectors.

Thirdly, the inversion should be between, but as close as possible to, two unique restriction enzyme sites in order for the construction of antisense clones to be convenient and easy. The two unique restriction enzyme sites can be either naturally existing or recombinantly created. In the case of antisense HIV-1 proviral clones, the chosen unique restriction sites are SalI and EcoNI, both of which occur only once in the whole plasmid pXE. The inversion is right before the EcoNI site but 4 bps after SalI site only to spare the vpr stop codon (TAG).

The sequences involved are 100% homologous between HIV-1 clones HXB2 and NL4-3 . The coding regions, however, are different. In HXB2, the sequence consists of 35-bp non-encoding area located between vpr and tat

(after the stop cod n of vpr and before the initiation cod n of tat). Of note is that the vpr in this clone is believed to have been truncated and rendered functionless. The inverted 171 bps sequence further consists of 136-bp in the tat-1 open reading frame where the first 45 amino acids are encoded, including all seven cysteine residues in TAT protein. As a result of the inversion, the following 27 amino acids of TAT-1 (#46-72) are also eliminated because of the frame-shift and the loss of initiation codon. In total, the 72-amino-acid TAT-1 protein is not made. In clone NL4-3, the coding for tat-1 is the same as HXB2, but the carboxyl terminus of vpr extends 55 bps into the inverted region, including a 20-bp overlap with tat-1. Vpr in clone NL4-3 is believed to be intact and functional. The two splice junction sites [splice donor (sd) and splice accepter (sa) are often collectively referred to as splice junctions] immediately before and after the area are not affected by the inversion. The inverted area, after transcribing into mRNA, is able to bind and block the natural HIV-1 mRNA specifically and effectively.

* * *

An antisense virus proviral molecular clone is constructed from a functional proviral molecular clone of a naturally occurring virus by inverting ("turning antisense") a section (i.e., part or all) of one or more genes. The inverted section of a selected gene is referred to as the "antisense fragment" herein. To be eligible for selection, the naturally occurring gene must meet two prerequisites. First, this gene must be required for the naturally occurring virus to replicate; and second, the gene must encode a protein product which is transactivating. Other genes are usually not affected during the antisense proviral molecular clone construction. In choosing the sequence of a gene to be inverted, special attention is paid to the gene involved and to its relationship to neighboring genes.

The sequence inversion can be accomplished by conventional recombinant technologies. A new strategy, however, has been developed to construct any antisense virus proviral molecular clone easily and

precis ly. Recombinant polymerase chain reaction (r-PCR or PCR) technology is employed. The PCR techn logy is kn wn to those skill d in the art. See U.S. patents 4,683,195 and 4,983,728 hereby incorporated by reference. The strategy of the subject invention (applicable to other viruses as well as HIV1) comprises the steps of:

1) Inserting DNA encoding a naturally occurring virus into a DNA cloning vector. Molecular cloning vectors such as plasmids (including phagemids), bacterial phage lambda and cosmids, are useful as cloning vectors.

2) Selecting a section of the viral DNA to be inverted. The selected section of the viral DNA is part or all of a gene that encodes a transactivating protein product which is required for the naturally occurring virus to replicate. The selected section of the viral DNA is flanked by a unique restriction enzyme site A at its 5' end and by another unique restriction enzyme site B at its 3' end. The unique restriction enzyme sites A and B are either naturally existing or recombinantly created;

3) Carrying out a polymerase chain reaction, using the selected section of the viral DNA as the template, and two specially designed "antisense primers" that target the selected section (in practice, the whole vector containing the whole proviral genome is typically used as the template - there is no need to isolate the selected section in view of the primers used). Antisense Primer 1 comprises at its 3' half a portion of DNA complementary to the 5' end of the selected section of the viral DNA, and at its 5' half a portion of DNA containing the unique restriction enzyme site B. Antisense Primer 2 comprises at its 3' half a portion of DNA complementary to the 3' end of the selected section of the viral DNA, and at its 5' half a portion of DNA containing the unique restriction enzyme site A. The PCR amplification product (the "antisense fragment"), when aligned with the naturally occurring section of the viral DNA, is antisense to the latter between the two unique restriction enzyme sites A and B;

4) Dig sting the vector containing the naturally occurring viral DNA with restricti n enzymes A and B t release the selected section of DNA;

5) Digesting the PCR amplification product with restriction enzymes A and B to release the antisense fragment;

6) Ligating the antisense section of DNA into the vector in place of the selected sense section of DNA; and

7) Isolating antisense virus proviral molecular clones by standard procedures of transforming appropriate strains of cells such as E. coli followed by colony screening.

See also Example 1.

Construction of Antisense HIV-2 Proviral Clones

Methods similar to those used above with HIV-1 are employed to construct antisense HIV-2 proviral clone(s). The construction starts with an infectious HIV-2 plasmid clone named pSE (Hu W et al. Virol. 173:624-630, 1989). A similar PCR strategy is applied to turn over the fragment between nt 5793 and nt 6062 totaling 270 bp in length (numbering according to Guyader M et al. Nature 326:662-669, 1987). This area covers the 3' portion of vpr and 5' portion of tat-1. Because HIV-2 VPR is dispensable for replication and cytopathogenicity (Dedera et al., J. Virol., 63:3205-3208, 1989), only TAT function has to be provided for the production of antisense HIV-2 viruses.

Construction of Antisense SIV Proviral Clones

Similarly, the construction of antisense SIV proviral clone(s) starts with full-length infectious SIVmac plasmid clone p239F (Kestler,

et al. Sci nce 248:1109-1112, 1990) or pK102 (Niederman t al. J. Virol. 65:3538-3546, 1991). Similar PCR strategies ar utilized to turn over the fragment between nt 5751 and nt 5988, totaling 238 bp in length (numbering according to Chakrabarti et al. Nature 328:543-547, 1987). This area also covers the 3' portion of vpr and 5' portion of tat-1. Because SIV VPR is probably dispensable for replication and cytopathogenicity, only TAT function has to be provided for the production of antisense SIV viruses.

Construction of Antisense Proviral Clones of Other Retroviruses

The construction strategies for antisense proviral clones presented herein apply to all retroviruses. The genes which can be turned antisense, partially or wholly, include all those with transactivation activity. Examples are as follows:

Tax and rex genes of human T-lymphotropic viruses (HTLV-1 and HTLV-2) and of bovine leukemia virus,

S gene of Visna Virus,

S1 and/or S2 genes of Equine Infectious Anemia Virus (EIAV)

(see SJ O'Brien ed. Genetic Maps, locus maps of complex genomes, 5th edition, book 1, viruses, CSH, 1990).

For the oncogene-containing oncoviruses (acutely transforming viruses, ATVs), the oncogenes contained, partially or wholly, are selected to be turned antisense.

Construction of Antisense Clones of Other Viruses

The antisense virus strategies also apply to viruses which contain DNA (not RNA) in their virions, provided that the virus at issue has one or more genes whose translation products are transactivating hence whose inactivation by sequence inversion can be compensated by gene products provided by a gene-expression vector (complemental expression vector), and that a cell culture system is available for making an antisense virus producer cell line. Examples of these viruses and the genes which can be turned antisense are:

X gene of hepatitis B virus,

E1A genes of adenoviruses,

E2 genes of papillomaviruses,

T genes of simian virus 40 and of polyomaviruses, and

genes encoding alpha proteins of herpes viruses

(see SJ O'Brien ed. Genetic Maps, locus maps of complex genomes, 5th edition, book 1, viruses, CSH, 1990).

* * *

ANTISENSE-RIBOZYME VIRUSES

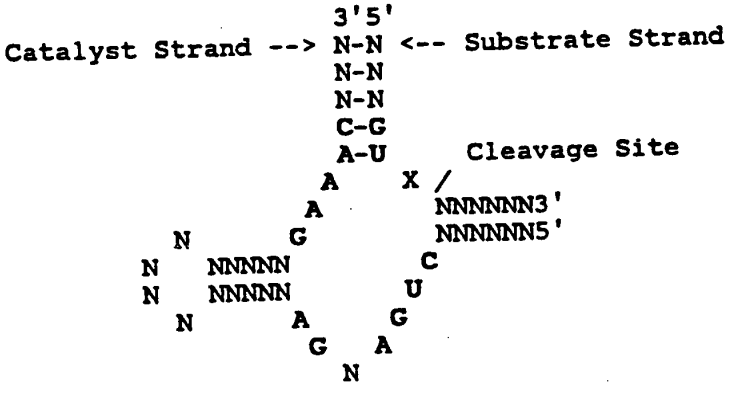

Antisense-ribozyme viruses are the same as antisense viruses but include one or more ribozymes in the antisense sequence(s) which cleave mRNA of the naturally occurring target virus.

The sequence inversion in the aforementioned HIV-1 antisense clones involved 171 base pairs. The sequence included 3' vpr (with pNL) and 5'

tat, where it covers the initiation methionine c don and all seven cysteine codons of tat gene. It is possible to form stabl c mplexes between the antisense RNA and the tat mRNA to block the latter from being translated into TAT protein. However, the formation of RNA complexes does not mean the destruction of the RNAs. On the contrary, the complex formation may provide protection to the tat mRNA against degradation in vivo. Ribozyme catalytic sequences incorporated into the antisense RNAs, however, are able to devitalize the bound mRNA molecules by cleaving them into pieces. The combination of antisense strategy with the ribozyme strategy magnifies the antiviral capability of the artificial viruses.

Ribozymes are RNA molecules that catalyze RNA cleavage [Cech, Science 236, 1532-9 (1987); Uhlenbeck OC., Nature (London) 328, 596-600 (1987) ; Forster et al, Cell 49, 211-220 (1987)], i.e., ribozymes are RNA that cut RNA. The simplest of the catalytic motifs of ribozyme is the autocleavage domain of certain plant pathogens (viroids) and viral satellite RNAs (virusoids) called the hammerhead (Forster et al, Cell 49, 211-220 1987). Some other forms from the continuously expanding list of ribozymes are those associated with the self-splicing large ribosomal RNA intron of Tetrahymena, the M1 RNA component of the Escherichia coli RNAse P enzyme, and another type of self-cleavage domains of plant viroid and virusoid RNA, the "hairpin" (Rossi JJ et al. AIDS Research and Human Retroviruses 8:183-9, 1992). The hammerhead consists of three stems and a catalytic center, all containing 13 conserved nucleotides:

5'GAAAC(N)nGUX(N)nCUGA(N)GA3'

Ribozymes, like protein enzymes, require specific structures for their catalytic activity. Natural catalytic centers may be formed by contiguous regions on the RNA or by regions separated by a large number of nucleotides. Cleavage by hammerhead ribozyme occurs 3' to the GUX triplet where X can be C, U, or A, generating 2', 3'-cyclic phosphate and 5' hydroxyl termini. The essential constituents of the hammerhead can be on separate molecules, with one strand serving as a catalyst and the other as a substrate. RNA sequences containing only the conserved cleavage domain (GUX) can serve as compatible substrates (Sarver, et al, Science 247, 1222-5 1990). Ribozymes have been attempted, with successes to various extent, as potential therapeutic agents for acquired immunodeficiency syndrome (AIDS) against gag (Sarver, et al. ibid), integrase (Sioud et al, Proc Natl Acad Sci U S A 88, 7303-7, 1991); vif (Lorentzen et al, Virus Genes 5, 17-23, 1991); and other sequences (Goodchild et al, Arch Biochem Biophys 284, 386-91, 1991). Ribozymes cleavage activity can be directed to cut very specifically pre-determined sequences on RNA molecules, both in cell-free system and within the cells, by the flanking RNA sequences which are antisense to the ribozyme's target, i.e., a ribozyme relies on antisense sequences to locate its positions of cutting. The antisense sequence binds to the mRNA and the ribozyme cuts the mRNA.

Construction of Antisense-Ribozyme HIV-1 Proviral Clones

The addition of RNA cleavage activity of ribozymes to increase the antisense virus's ability to neutralize a naturally occurring virus was accomplished by incorporating one or more of the 22-nucleotide-long catalytic domains, containing the consensus sequence, into the antisense sequences. The ribozyme(s) will cut the tat mRNA at 3' to the triplets GUX (X = A, C or U) which occur eight times in the area that has been turned antisense. While three of the GUX have actually been chosen, any one of them is potentially a target site for ribozyme cleavage. The designing procedure is illustrated as follows:

The original sequences between nt 5775 and 5986 of pX are as below.

The b ld-type area is where the inversion ccurs.

G     G     U
 U   A
  C A
```

can be fixed into the antisense sequence to replace any one or more of the nucleotides indicated by a "*" on top. The ribozyme will thus be targeted to cut the sense RNA 3' to the triplet "GTX" where "X" stands for "A", "G" or "U".

See Example 3 for a detailed description of construction of ribozyme proviral clones.

Construction of Antisense-Ribozyme HIV-2 Pr viral Cl nes

A ribozyme catalytic sequence can also be incorporated into the HIV-2 antisense clone to cleave (GUU) the tat mRNA at any one or more positions of 5883-5885 (GUC), 6011-6013 (GUA), 6032-6034 (GUC), and 6041-6043 (GUU). These are the four GUX positions in the area to be turned antisense (nt 5793-6062).

Construction of Antisense-Ribozyme SIV Proviral Clones

A similar ribozyme sequence can also be implanted to the antisense SIV proviral clone(s) to target mRNA at positions 5767-5769 (GUA) or/and positions 6063-6065 (GUU). The 5767-5769 GUA triplet is 18 bases before the tat initiation codon. The cleavage, however, deprives the tat mRNA of leading sequence necessary for its translation into protein. The 6063-6065 GUU sequence is at SIV tat amino acids 59-60.

Construction of Antisense-Ribozyme Viral Clones of Other Viruses

The same or similar ribozyme sequences can also be fixed into other antisense viral clones wherever a "GUX" triplet is present in the sense mRNA sequences.

COMPARISONS OF NATURAL, ANTISENSE AND ANTISENSE-RIBOZYME HIV-1 MOLECULAR CLONES

A. Natural (Wild Type) HIV-1 Clones (pXE or pX or pNL4-3)

1. Contain intact LTRs, gag, pol, env, vif, vpr, tat, rev, vpu, nef genes.

2. Replication competent: produce normal virions.

3. Inf ctious: virions carry on their envelope membranes normal gp120 and gp41. Gp120 is capable of attaching to CD4 molecules (act as receptors for the viruses) and introducing the virion contents into the cells.

4. Pathogenic: viral components are synthesized, virions assembled and exported, resulting in the death of host cells.

5. Cause Illness: mainly because of CD4(+) lymphocyte depletion and subsequent opportunistic infections and tumors.

B. Antisense HIV-1 Molecular Clones (pXE-a & pXE-b)

1. Contain intact LTRs, gag, pol, env, vif, vpr, vpu genes. A portion of tat-1 gene is inverted. Rev is either intact (pXE-a) or abraded (pXE-b).

2. Replication impaired, but can be complemented by transactivating factor tat (and rev for pXE-b). In the existence of tat (and rev) protein to provide necessary regulation, replication capability is restored, though may not necessarily be complete. Virus particles can be formed which are otherwise normal except carrying inverted tat-1 sequence (and the mutated rev initiation codon).

3. The assembled virions are infectious in that they can bind t CD4 molecules, can be taken up by CD4(+) cells, be reverse-transcribed into double-stranded DNA, be transported to the cell nucleus, and be integrated into the cellular genome. In the event that the cells are activated and dividing, the integrated proviral sequences will also be copied into each daughter cell along with the cellular DNA. In the absence of the essential tat (and rev) protein(s), however, the proviral sequences cannot produce virus particles.

4. These replication-impaired HIV-1 derivatives are non-pathogenic.

5. They cann t make pe ple ill.

6. In the presence of tat (and rev) protein(s), provided either by expression vectors or by naturally infecting HIV-1 viruses, the inert provirus can be re-activated; the provirus can be transcribed into mRNA and translated into proteins with the exception of tat and, in some cases, vpr and rev.

7. The expressed antisense tat RNA can bind and inactivate the natural sense tat mRNA, consequently inactivating the natural viruses.

C. Antisense-Ribozyme HIV-1 Molecular Clones (pXE-ar, pXE-br)

1. Contain intact LTRs, gag, pol, env, vif, vpr, vpu genes. A portion containing tat-1 is inverted and one or more ribozyme catalytic domains have been inserted in such portion. The rev gene is either intact (pXE-ar) or inactivated (pXE-br).

2. Replication impaired, but can be complemented by transactivation factor, tat (and rev for pXE-br). In the existence of tat (and rev) protein to provide necessary regulation, replication capability are restored, though may not necessarily be complete. Virus particles can be formed which are otherwise normal except carrying inverted tat-1 sequence and one or more ribozyme catalytic domains (with mutated rev initiation codon in pXE-br).

3. The assembled virions are infectious in that they can bind to CD4 molecules, can be taken up by CD4(+) cells, be reverse-transcribed into double-stranded DNA, be transported to the cell nucleus, and be integrated into the cellular genomes. In the event that the cells are activated and dividing, the integrated proviral sequences will also be copied into each daughter cell. In the absence of the essential tat (and rev) protein(s), however, the proviral sequences cannot produce the virus particles.

4. Non-path genic.

5. They cannot make people ill.

6. In the presence of tat (and rev) protein(s), provided either by expression vectors or by naturally infecting HIV-1 viruses, the inert provirus can be re-activated; the provirus can be transcribed into mRNA and translated into proteins with the exception of tat and, in some cases, vpr and rev.

7. The expressed antisense tat RNA can bind and inactivate the natural sense tat mRNA. Moreover, the tat mRNA is cut into pieces by the incorporated ribozymes. Consequently the natural viruses is eliminated.

Antisense/Ribozyme Clone Functionality Tests

1. The natural HIV-1 clone, pX or pXE, when transfected alone, produces viruses which replicate rapidly as indicated by RT (reverse transcriptase) activity, viral protein detection, syncytium formation, and cell killing - positive control.

2. The antisense/ribozyme recombinant clone(s), when transfected alone, do not produce virus, as indicated by background RT activity, no syncytium formation, normal cell growth.

3. An antisense/ribozyme clone produces viruses if co-transfected with a positive TAT-expression clone, or if transfected into cells constitutively expressing TAT protein, as indicated by raised RT activity, viral protein detection, possible syncytium formation, possible cell killing.

4. Supernatant from cultures co-transfected with an antisense/ribozyme clone and a TAT-expressing clone contains virus particles (EM visible, RT activity, p24 ELISA, etc.).

5. Virus particles contained in the co-transfected supernatant can be taken up by CD4(+) cells.

If the cells contain TAT, new viruses are produced as indicated by RT, p24, and cytopathagenesis.

If the cells do not contain TAT, they will grow normally, even though the antisense/ribozyme proviral sequences might have integrated into the cellular DNA.

6. An antisense/ribozyme recombinant clone co-transfected with a natural clone results in a period of time during which both clones are replicating as indicated by a considerable rise of RT activity, viral protein detection, syncytium formation, even cell killing. After that period of time, however, RT drops gradually, syncytia disappear, and cells grow normally.

7. If both supernatants from natural clone-transfected culture and antisense/ribozyme recombinant clone-transfected culture is used to infect normal CD4+ cells, infection occurs and production of virus occurs briefly, then the cells gradually return to normal with the viruses eliminated.

8. Virus particles can be purified from cell cultures co-transfected with a antisense/ribozyme proviral clone and a TAT-expression clone.

9. Introduction of purified antisense/ribozyme viruses into cell cultures producing natural viruses results in gradual decrease and eventual cessation of natural virus as well as antisense/ribozyme virus production.

10. When purified antisense/ribozyme virus particles are administered to patients infected with HIV-1, virus production decreases

gradually and ventually ceases.

Individualization of Antisense/Ribozyme Viruses

Individualization of an antisense/ribozyme virus is achieved with an individualized antisense/ribozyme proviral clone. An individualized antisense/ribozyme proviral clone is constructed by replacing a selected section of a gene of an existing functional proviral clone with an individualized antisense/ribozyme fragment. This individualized antisense/ribozyme fragment is synthesized in a single PCR reaction, using as the template the nucleic acid specimen from a particular patient which contains integrated or unintegrated viral sequences. The antisense/ribozyme primers are the same as detailed above. The PCR products are used to replace the corresponding section of a gene in the existing proviral molecular clone. The resultant recombinant clone has an individualized antisense/ribozyme fragment which, when expressed into RNA forms a perfect duplex with (and in the case of an antisense ribozyme virus - cleaves the mRNA of) the particular virus strain infecting the particular patient. With individualization of antisense/ribozyme virus, it is only necessary to individualize the antisense/ribozyme fragment. The other components of the viral genome are those of any existing functional virus clone available.

Individualization for treatment is a distinct advantage of the subject invention. Mutation permits the AIDS virus to escape and finally destroy the human immune system. Individualization of antisense/ribozyme viruses is an effective way to neutralize the mutating AIDS viruses.

The individualization method discussed are applicable to HIV-1, HIV-2 and SIV viruses as well as other viruses (as discussed above).

C mplemental Gene Expression Vectors

The antisense/ribozyme molecular clones, as mentioned above, cannot replicate on their own. In the case of HIV, when the antisense/ribozyme clones are transfected into cells, the cells do not make viruses because the clones are missing the tat (and rev) gene function(s). For the cells to be able to make viruses, the cells must provide tat (and rev) gene protein(s) which are necessary for, but are not produced by, the antisense/ribozyme clones. Gene-expression molecular clones have therefore been designed to provide tat, optionally rev and vpr, functions which are missing from the antisense/ribozyme clones because of sequence inversion. pX and pNL are used for the construction of gene-expression clones.

One of three following methods is employed.

The first method is to truncate major genes of HIV-1 except tat, rev and vpr (which overlap with each other). In practice the coding region for env is also kept intact along with the long terminal repeats (LTRs). The truncated clone, when introduced into cells, expresses tat and rev which trans-activate the antisense/ribozyme clones. Env and vpr proteins also are expressed which can help the antisense/ribozyme virus assembly.

The second method is to insert the tat (and rev as well) coding sequences into gene expression vectors driven by promoters from sources other than HIV-1.

The third option is to insert chemically synthesized tat-coding DNA sequence into one of the many gene expression vectors commercially available. Many gene-expression vectors are commercially available for expressing a cloned gene in mammalian cells. Such gene-expression vectors are described in detail in at least two laboratory manuals (Sambrook J, Fritsch EF & Maniatis T. Molecular Cloning, a laboratory manual, second edition, Cold Spring Harbor Laboratory Press, 1989, chapter 16; Kriegler M. Gene transfer and expression, a laboratory

manual, Stockt n press, 1990, chapter 2). The ch ice of a vector is based on the gene to be expressed and the h st cells in which the gene will be expressed. For expressing HIV-1 TAT (and REV) proteins in CD4+ cell lines of human origin, for example, a retrovirus long terminal repeat (LTR)-driven gene-expression vector can be used (Rosen CA et al. 1986. J Virol 57:379-384; Vickers T et al. 1991. Nucleic Acids Res 19:3359-68; Rhodes A & James W. 1991. AIDS 5:145-51). An advantage of using HIV-1 LTR-driven gene-expression vectors to express HIV-1 TAT protein (Guyader M et al. 1987. Nature 326:662-9) is the reciprocal augmentation of the transcriptional activation and the gene-expression product. Other promoters which have been used to express HIV genes are SV40 regulatory sequences (Arya SK et al. 1985. Science 229:69-73; Dillon PJ et al. 1991. J Virol 65:4490-3), Drosophila hsp70 promoter (Schweinfest CW et al. 1988. Gene 71:207-10), SR-a (Mallon R et al. 1990. J Virol 64:6282-5).

For selecting only the expression-vector-containing cells, neomycin resistance gene expression cassettes are inserted into the expression vectors. With the inclusion of antibiotic G418 in the culture medium, only those cells transfected with Neo(r) gene (together with HIV-1 tat and other genes) survive, assuring that every cell in the culture has the capability to support the making of antisense/ribozyme viruses.

All principles and methodologies presented for constructing the gene expression vector clones apply to HIV-2, SIV and other viruses as well as to HIV-1. Examples of construction of these vectors are shown in the Examples 5-7 below.

Antisense/Ribozyme Virus Producer Cell Lines

Transfection of either an antisense/ribozyme proviral clone or a tat-expression vector alone into cells does not result in the production of antisense/ribozyme virus. It is necessary to introduce both the antisense/ribozyme proviral clone and the tat-expression vector into the same cell in order for the antisense/ribozyme virus particles to be

made. Practically, a tat-expression vector can be transfected into a cell line (Jurkat for example), selected by including G418 in the cultur medium, tested for the production of tat and other proteins, then kept in cell culture or frozen for later transfection of the antisense/ribozyme proviral clones. It has been shown that the Jurkat cell line can be stably transfected with a plasmid that constitutively expresses antisense tat RNA even after eight months in cell cultures (KostR et al, Clin Res; 38(2):278A, 1990). It can be expected that the same cell line will also be able to be stably transfected with a plasmid that constitutively expresses sense tat RNA (mRNA) and protein.

Advantageously, the antisense/ribozyme virus producer cell lines for HIVs are CD4+ and of human origin. CD4 positivity ensures that, once the cell line has been engineered to constitutively express TAT (and/or other) protein, the antisense/ribozyme virions released from one cell will be capable of infecting other cells in the culture, enabling quick production of large quantities of antisense/ribozyme virus stocks. Human origin of the producer cell lines minimizes the possibility of provoking adverse immunoreactions by the antisense/ribozyme inocula.
Advantageously, the above mentioned Jurkat, a CD4+ lymphoid cell line frequently utilized to express HIV-1 genes (Venkatesh LK et al. PNAS 87:8746-50,1990; Maitra RK et al. Virology 182:522-33, 1991), will be a good choice as an antisense/ribozyme virus producer cell line. Other CD4+ lymphoid cell lines such as H9, HUT78, MT4, CEM, MOLT4, and monocyte/macrophage cell lines such as U937, THP-1, AND GCT, frequently used in HIV-1 transfection experiments (Aldovini A & Feinberg MB. 1990. Transfection of molecularly cloned HIV genomes. in Techniques in HIV Research, A. Aldovini & BC Walker, eds, Stockton Press, pp147-175), are useful for HIV-1 antisense/ribozyme virus producer cell lines. Some adherent cell lines, that are normally not susceptible to infection yet capable of expressing HIV genes and producing virus upon transfection, are regularly employed in studies of HIV gene regulation (ibid). The HeLa cell lines, for example, either CD4-negative (Mallon R et al. J Virol. 64:6282-5,1990) or better CD4-positive, HeLaCD4 and HeLaT4+ (Schroder HC et al. FASEB J 4:3124-30, 1990) can be used for HIV-1

antisense/rib zyme virus producer cell lines. The 293 human embry nic kidney cell line, which supports high levels of expressi n f HIV trans-activation (Jakobovits A et al. EMBO J 9:1165-70, 1990), is another good host cell line.

For producer antisense/ribozyme virions for other viruses, other cell lines are chosen according to considerations known to those skilled in the art.

Cell line transfected with one of the HIV-1 tat-expression vectors are cultured in medium supplemented with antibiotic G418, and the surviving cells are tested for the production of HIV-1 proteins.

pX-CSneo transfected cells express vpr, tat, rev, and env proteins; while pX-neo transfected cells express no viral proteins.

SFneo-t/r(+) transfected cells express tat protein, and possibly rev protein; while SFneo-t/r(-) or SFneo transfected cells produce no HIV-1 protein.

SFneo-tat(+) transfected cells express tat protein only; while SFneo-tat(-) or SFneo transfected cells produce no HIV-1 protein at all.

If TAT activity is detected (by CAT assay), the transfected cells are propagated. Part of the cells are frozen. Another part are passed through long-term culture to test the stability of TAT gene expression. Cells stably expressing TAT and other proteins are used as antisense/ribozyme virus producer cells and are transfected with HIV-1 antisense/ribozyme clones. The doubly transfected cells are assayed f r the production of HIV-1 viruses (antisense/ribozyme viruses). P24 ELISA, RT activity and electronic microscopy are employed to detect the presence of the viruses.

If the cells are producing the viruses, the conditioned medium (containing virus particles), optionally concentrated, is used to infect

CD4(+) cells (H9, Molt-3, CEM, U937, etc.) and the producti n of progeny viruses is assayed.

When a cell line is transfected with an HIV-2 or SIV TAT-expression vector, it becomes an antisense/ribozyme virus producer cell line for HIV-2 or SIV.

Compositions of the Invention

Also comprehended by the invention are pharmaceutical compositions comprising therapeutically effective amounts of products of the invention together with suitable diluents, preservatives, solubilizers, emulsifiers, adjuvants and/or carriers useful in antiviral therapy. A "therapeutically effective amount" as used herein refers to that amount which provides a therapeutic effect for a given condition and administration regimen. Where a product of the subject invention is used as a prophylactic medicine, a therapeutically effective amount is that amount which prevents infection.

The compositions of the invention are liquids, gels, ointments, or lyophilized or otherwise dried formulations and include diluents of various buffer content (e.g., Tris-HCl., acetate, phosphate), pH and ionic strength, additives such as albumin or gelatin to prevent adsorption to surfaces, detergents (e.g., Tween 20, Tween 80, Pluronic F68, bile acid salts), solubilizing agents (e.g., glycerol, polyethylene glycol), anti-oxidants (e.g., ascorbic acid, sodium metabisulfite), preservatives (e.g., Thimerosal, benzyl alcohol, parabens), bulking substances or tonicity modifiers (e.g., lactose, mannitol), covalent attachment of polymers such as polyethylene glycol to the protein, complexation with metal ions, or incorporation of the material into or onto particulate preparations of polymeric compounds such as polylactic acid, polyglycolic acid, hydrogels, etc. or into liposomes, microemulsions, micelles, unilamellar or multilamellar vesicles, erythrocyte ghosts, spheroplasts, skin patches, or other known methods of releasing or packaging pharmaceuticals. Such compositions will influence

the physical state, s lubility, stability, rate of in vivo rel ase, and rate of in vivo clearance of the antisense and/or antisense-ribozyme viruses. The choice of composition will depend on the physical and chemical properties of the antisense and/or antisense-ribozyme viruses. Controlled or sustained release compositions include formulation in lipophilic depots (e.g., fatty acids, waxes, oils). Also comprehended by the invention are particulate compositions coated with polymers (e.g., poloxamers or poloxamines). Other embodiments of the compositions of the invention incorporate particulate forms protective coatings, protease inhibitory factors or permeation enhancers for various routes of administration, including parenteral, pulmonary, nasal, topical (skin r mucosal) and oral.

The invention also comprises compositions including one or more additional antiviral factors such as 3'-azidodeoxythymidine (AZT) or dideoxycytidine (ddC). The administration of antisense and/or antisense-ribozyme viruses with other antiviral agents, is temporally spaced or given together. The route of administration may be intravenous, intraperitoneal sub-cutaneous, intramuscular, topical, oral or nasal.

Antisense and/or antisense-ribozyme viruses of the invention may be "labelled" by association with a detectable marker substance (e.g., radiolabeled, enzyme labelled, or biotinylated).

The following examples are offered to more fully illustrate the invention, but are not to be construed as limiting the scope thereof.

THE EXAMPLES

Example 1: PCR STRATEGY FOR ANTISENSE CONSTRUCTION

A PCR strategy was developed to accomplish the sequence inversion (flip-over). For ease in understanding, the amino acid sequences encoded

by the DNA is not shown and the c mplementary DNA strand (negative strand, antisense strand, written in small characters) is shown for the DNA sequence of the tat gene to be inverted:

ATGGCAGGAAGAAGCGGA-3'
taccgtccttcttcgcct-5'
Eco-NI
```

A special design for the primers (antisense primers) is essential for the recombinant PCR strategy to be successful and convenient. Basically, each antisense primer comprises two parts which are separated in the natural DNA sequence: an annealing sequence corresponding to one end of the 171-bp fragment to be turned over and a 15-base tail from the other side immediately beyond the area to be inverted. The 5' antisense primer is to anneal to the negative strand at the beginning of the sequence to be inverted, but it has a 15-base tail whose sequence corresponds to the 15 bases right after the sequence to be inverted where the unique EcoNI site is located. On the other hand, the 3' antisense primer is to anneal to the positive strand at the end of the sequence to be inverted, but it has a 15-base tail whose sequence corresponds to the 15 bases right before the sequence to be inverted where the unique SalI site is located. In the primers shown below, capital letters represent sequence from positive (sense) strand and small letters are used for the negative (antisense) strand.

Upper Line: Antisense RNA sequence, written 5'-->3';
Lower line: Natural mRNA sequence, written 3'-->5'.

By binding together, the natural mRNA and the antisense RNA block each other from being translated into proteins, resulting in the depletion of tat protein, and subsequently all viral proteins, for the natural as well as the antisense HIV-1 viruses.

==========

For eliminating the rev gene at the same time, the rev initiation codon was changed into a non-initiation one:

CAATGAAAGC AACACTTTTT ACAATAGCAA TTGGTACAAG CAGTTTTAGG 100

CTGACTTCCT GGATGCTTCC AGGGCTCTAG TCTAGGATCT ACTGGCTCCA 150

TTTCTTGCTC TCCTCTGTCG AGTAACGCCT ATTCTGCCTA GGGCAGGAAG A 201

Note that SEQ ID NO:5 is only a single base pair different from SEQ ID NO:3, i.e., the base at position 191 is a "T" in SEQ ID NO:3 but a "G"

in SEQ ID NO:5.

Rev(-) antisense molecular clones can be made by replacing the original SalI-EcoNI fragment on pXE with the SalI-EcoNI fragment on SEQ ID NO:5.

The flip-over PCR system consisted of:

pX, 1 µg/ml		2 µl
Reaction buffer, 10x		5 µl
Tris-HCl, pH8.3	500 mM	
KCl	500 mM	
MgCl2	20 mM	
Gelatine	0.05 %	
dNTP, 2.5 mM each		3 µl
Primer Tvpr 5965, 60 µg/ml		2 µl
Primer Trev 5795, 60 µg/ml (or Trev[-]5795)		2 µl
AmpliTaq DNA polymerase, 5 u/µl (from Perkin Elmer Cetus)		0.2 µl
Double distilled water		35.8 µl
		50.0 µl

The samples, with proper controls, were run on a DNA Thermal Cycler (Perkin Elmer Cetus) for 35 cycles each consisting of 94°C for 20 seconds, 60°C for 20 seconds and 74°C for 30 seconds.

10 µl of each PCR product was run on agarose gel (NuSieve 3:1, FMC). The correct size of the PCR product is 201 base pairs, which was confirmed by agarose gel electrophoresis.

Each inverted PCR product (antisense fragment) was extracted with phenol-chloroform-isoamyl alcohol (25:24:1), precipitated with alcohol and resuspended in 20 µl of TE solution (10 mM Tris-HCl, pH 7.5 and 1 mM EDTA). The purified PCR product was then mixed with plasmid DNA of pXE and digested with both restriction enzymes SalI and EcoNI:

Inv rt d PCR pr duct, extracted		5 µl
pXE, 500 µg/ml		2 µl
Reaction buffer, 10x		5 µl
Tris-acetate, pH 7.9	20 mM	
Magnesium acetate	10 mM	
Potassium acetate	50 mM	
DTT	1 mM	
EcoNI, 15 u/µl, NEB		1 µl
Sal I, 10 u/µl, NEB		1 µl
Double distilled water		37 µl
		50 µl

Incubation was at 37°C for at least 3 hours.

Ten microliter of the digest was run on agarose gel to make sure that the digestion had been satisfactory. The digest was heat-inactivated at 65°C for 10 minutes and used directly for ligation:

Above digest, undiluted	4 µl
Ligase reaction buffer, 5x	4 µl
T4 DNA ligase, 1 u/µl, BRL	1 µl
Double distilled water	11 µl
	20 µl

Incubation was at 15°C for at least 3 hours.

The PCR-derived SalI - EcoNI fragment, containing the inverted sequence and outnumbering the plasmid-derived SalI -EcoNI fragment, competitively inserted itself into the SalI and EcoNI sites of the plasmid molecule.

One microliter of the 10-fold dilution of the ligation was used to transform 20 µl of competent HB101 E. Coli cells according to the instruction of the manufacturer (BRL). Briefly, 1 µl of the diluted ligation was gently mixed with the cells in a 1.5 ml microcentrifuge tube. After placing in ice for 30 minutes, the cells were heat shocked at 42°C for 45 seconds then quickly returned to ice for two more minutes. 180 µl of S.O.C. Solution (2% tryptone, 0.5% yeast extract, 10 mM NaCl, 2.5 mM KCl, 10 mM MgCl2, 10 mM MgSO4, 20 mM glucose) was added and mixed, then the tube was incubated at 37°C with constant agitation for 1 hour. The cells were spread on LB agar plate supplemented with

ampicillin to the final concentration of 50 µg/ml. The plat was incubated at 37°C overnight. Colonies were picked into 2 ml LB medium supplemented with ampicillin (LBamp) in the final concentration of 50 µg/ml. The bacterial cultures were placed at 37°C shaker-incubator overnight.

The bacteria were harvested and miniplasmid DNA extracted according to Sambrook, Fritsch and Maniatis (Molecular Cloning, a laboratory manual, second edition, Cold Spring Harbor Laboratory Press, 1989) with minor modifications as necessary. Briefly, 1.5 ml of each overnight culture was pipetted into a microcentrifuge tube and spun in tabletop microcentrifuge for 1 minute. The pellet was completely dispersed in 100 µl of Solution I (50 mM glucose, 25 mM Tris-HCl pH 8.0, 10 mM EDTA pH 8.0). After adding 200 µl of freshly prepared Solution II (0.2 N NaOH, 1% SDS), the tube was inverted several times to mix. 150 µl of cold Solution III (5 M potassium acetate 60 ml, glacial acetic acid 11.5 ml, H2O 28.5 ml) was added and the tube vortexed briefly. The tube was then microcentrifuged for 2 minutes, the supernatant transferred to a new tube and extracted once with phenol:chloroform:isoamylalcohol (25:24:1). Plasmid DNA was precipitated with 1 ml of 100% ethanol, washed once with 75% ethanol, air-dried and resuspended in 30 µl of TE solution (10 mM Tris-HCl pH 7.5, 1 mM EDTA).

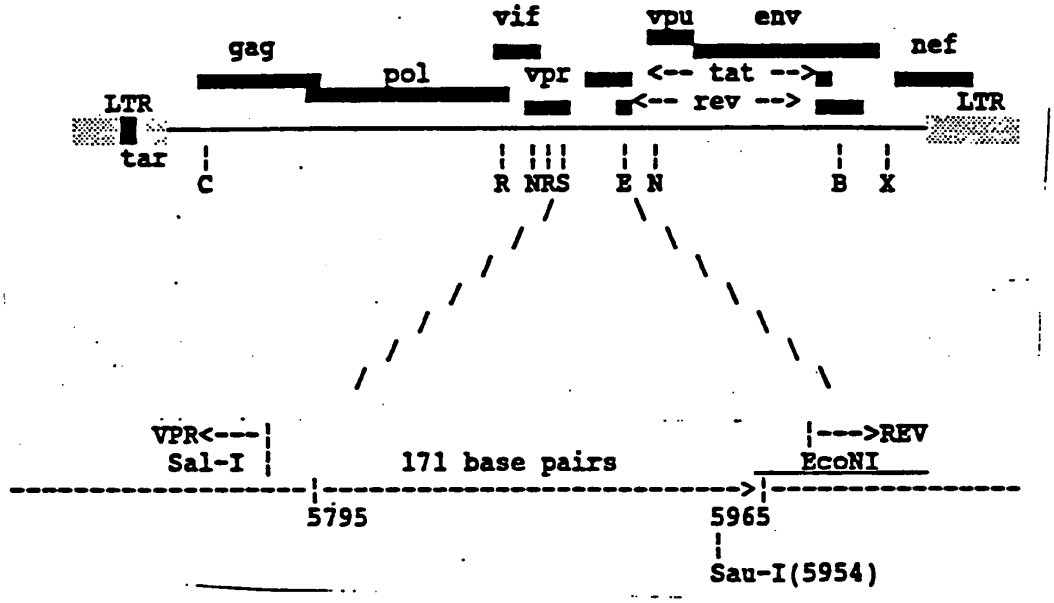

Example 2: SCREENING FOR ANTISENSE MOLECULAR CLONES

Miniplasmids were screened for the antisense molecular clones primarily by restriction endonuclease digestion followed by agarose gel electrophoreses. The clone constructed with Trev(+) primer was named pXE-a, and the clone constructed with Trev(-) primer was named pXE-b.

Comparing the original with the antisense proviral molecular clones, the Sau-1 (Bsu36I) restriction enzyme site at the original position 5954 has been moved to position 5800 in the antisense clone. The different positions of this Sau-I site in the natural versus antisense clone is employed for easy screening for the antisense clones.

AS= Antisense B = BamHI C = ClaI E = EcoNI

Restriction Digestion Patterns of Molecular HIV-1 (HXB2) Full-Length Clones and Major Subclones.

If the exact size of a particular fragment (band) is known, it is indicated by the exact number in bp (base pairs); If the exact size is not known, the estimated size is indicated by kb (kilobase). Bold-type are major clones or bands of interest for the particular restriction enzyme digestion.

X = pX E = pXE Ea = pXE-a Eb = pXE-b
Ear = pXE-ar Ebr = pXE-br N = pX-N NE = pX-N-E
E2 = pX-E2 E = pXE XCS = pX-CS

Bsu36I (SauI)

	X	E	Ea	Eb	Ear	Ebr	N	NE	E2	E	XCS
13.0kb	-	-	-	-	-	-	-	-	-	-	
8.5kb											-
1695bp	-	-	-	-	-	-	-	-	-	-	-
1514bp			-	-	-*	-*					
1360bp	-	-							-	-	-
0.7kb	-	-	-	-	-	-	-	-	-	-	-

* This band is 21 base pairs larger than 1514 in pXE-ar and pXE-br because of the inclusion of the ribozyme catalytic sequence.

Bsu36I (SauI) is an excellent choice for distinguishing antisense/ribozyme proviral clones from the wild type clones (either pX or pXE). The 1360-base-pair wild type band changes to 1514 base pairs in antisense clones and to 1535 in antisense-monoribozyme clones. For the antisense-bi- and tri-ribozyme clones (not listed in the chart), this band will become 1556 (1514 + 21x2) and 1577 base pairs (1514 + 21 x 3). When samples are run side by side, the distinction between wild type clones and antisense/ribozyme clones is unmistakably obvious.

Note: The restriction sites are cited fr m GeneBank. The SauI site at nt 2252 is missing in pX as is in pXE. Missing with the site is the 3702-bp band.

Restriction digestion patterns of molecular HIV-1 (HXB2) full-length clones and major subclones.

AvrII

	X	E	Ea	Eb	Ear	Ebr	N	NE	E2	E	XCS
3420bp	-	-	-	-	-	-	?	?	-	-	?
2339bp	-	-	-		-		?	?	-	-	?
2033bp				-		-					
306bp				-		-					
230bp	-	-	-	-	-	-	?	?	-	-	-

These restriction site reorganizations were confirmed by individual or combined enzyme digestion followed by agarose gel electrophoreses.

Armed with 171-base antisense RNA targeted to the essential tat gene of HIV-1 while still carrying all information of HIV-1, the antisense proviral clones pXE-a and pXE-b will make artificial antisense viruses which will neutralize the natural HIV-1 viruses.

Open Reading Frames in the Inverted Sequence

Analyzing the inverted 171 base pairs, two open reading frames (ORFs) were found with methionine initiation codon of 12 and 25 amino acids in length respectively. Global screening of PC/gene data bases has found no match, even allowing up to eight mismatches. The binding by natural mRNA blocks the formation of these putative proteins, just as it blocks the natural mRNA.

Open reading frames with methi nine initiation c d ns:

Example 3: ANTISENSE-(MONO)RIBOZYME PROVIRAL CLONES

The 22-nucleotide-long catalytic domain was fixed into the antisense sequences to replace a "G", and thus was directed to cut the sense RNA at GUC which occurs once on tat mRNA:

```
CAGAAUUGGGUGUCGACAUAGAGAUGCCUAAGGCUUUUGUUAUGAAACAAACUUGGCAAUGAAAG
                         !!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
AGGCGAAGAAGGACGGUAUCCUCUACGGAUUCCGAAAACAAUACUUUGUUUGAACCGUUACUUUC
```

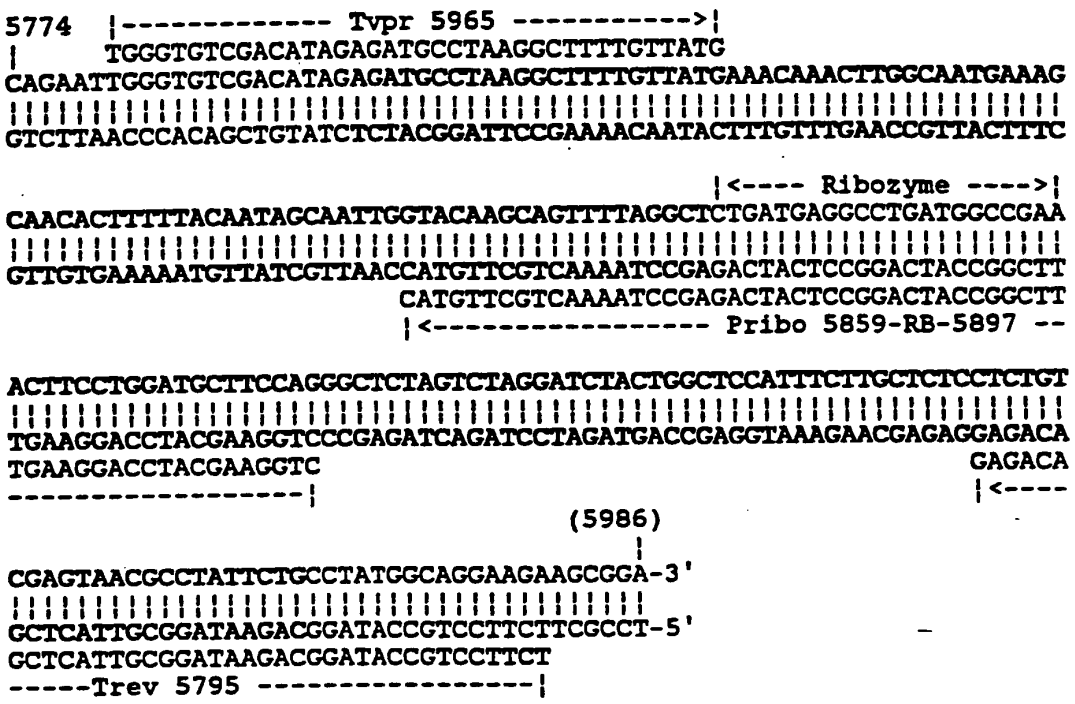

Upper Line: Antisense RNA sequence, written 5'-->3', with one ribozyme catalytic domain incorporated.

Lower line: Natural mRNA sequence, written 3'-->5', with all potential ribozyme cleavage sites underlined.

The antisense RNA sequences with the incorporated ribozyme domain are written into DNA with complementary sequences added.

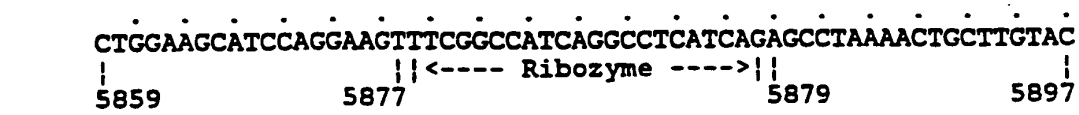

PCR technology was utilized to incorporate the ribozyme catalytic

domain. To acc mplish this, three primers were designed which c rresp nd to the positions sh wn below.

Primers "Tvpr 5695" and "Trev 5795" are actually SEQ ID NO:2 and SEQ ID NO:1 as aforementioned for antisense PCR. Therefore, only one more primer (Pribo) was needed to make the antisense-ribozyme proviral clone.

Pribo 5859-RB-5897, numbering is of the wild type sequences:

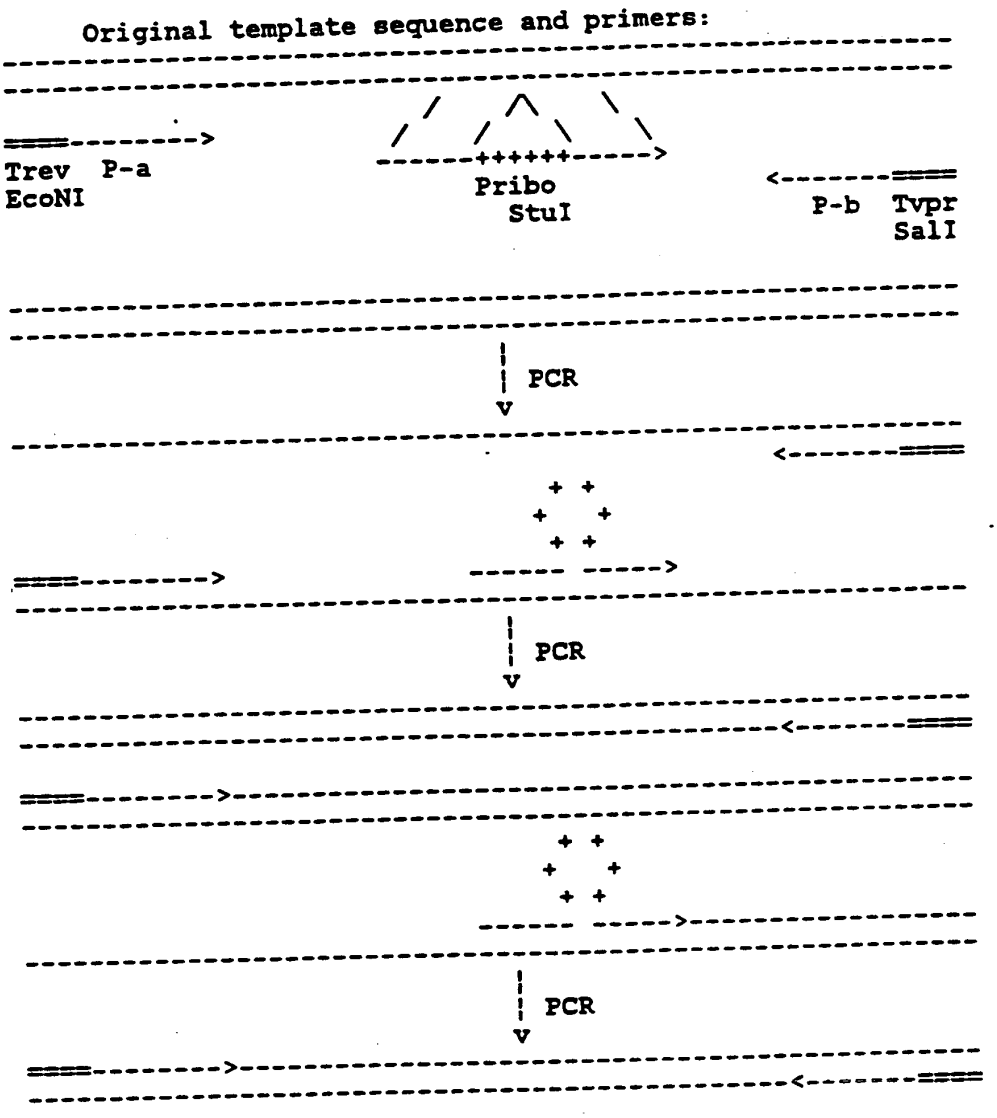

SEQ ID NO:6

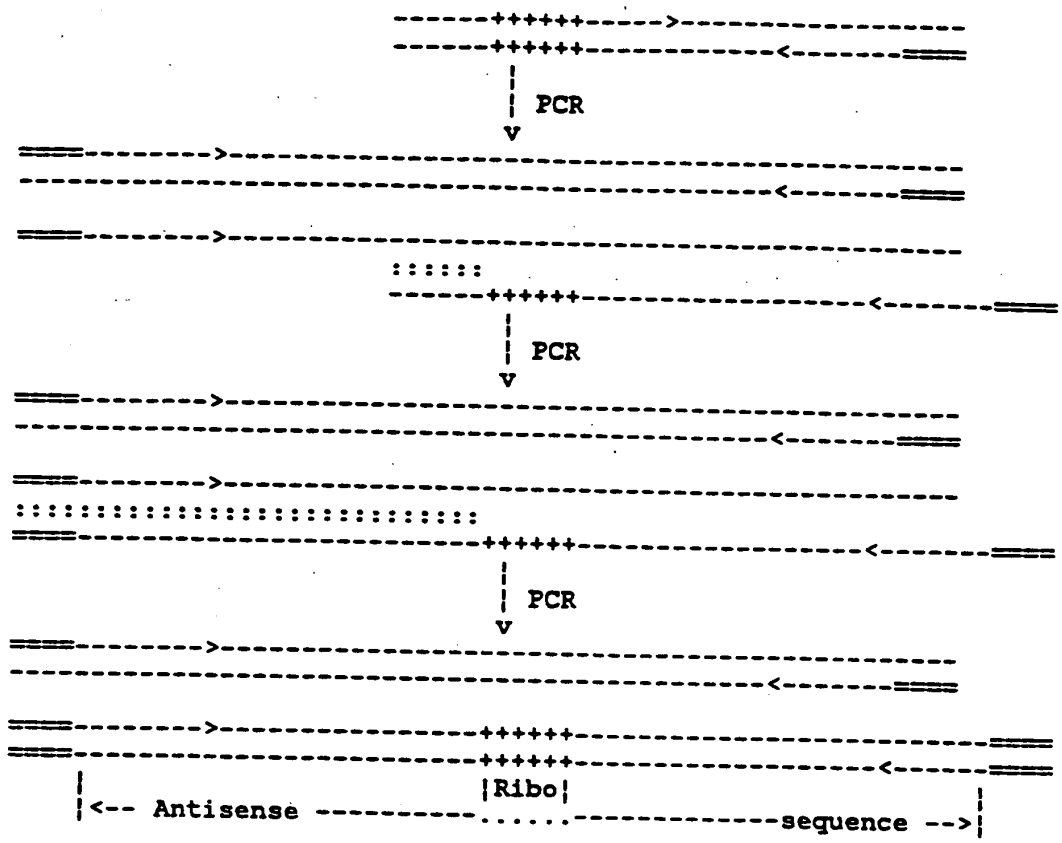

CTGGAAGCAT CCAGGAAGTT TCGGCCATCA GGCCTCATCA GAGCCTAAAA 50

CTGCTTGTAC 60

The following graphs illustrate how the Pribo primer inserts the ribozyme sequence into the PCR products. All three primers were put into the PCR system, with Pribo at a concentration about one tenth the

conc ntration of either f the two end primers. pX was chosen as template. All full length clones, i. ., pXE, pXE2, pXE-a, pXE-b and pNL are all eligible for being templates and will result in the same PCR product, with the Pribo primer inserted its sequence into some of the amplified DNA fragments.

PCR product without ribozyme sequence is 201 bps, while that containing ribozyme sequence would be 222 bps as follows.

```

pXE together with "antisense-ribozyme PCR" product were digested with SalI and EcoNI simultaneously then self-ligated. The ligation was used to transform competent HB101 cells as detailed in the Examples. Miniplasmids were screened by digesting with StuI restriction enzyme (see below).

The genomic organization of the rev(+) antisense-(mono)ribozyme clone, pXE-ar(2):

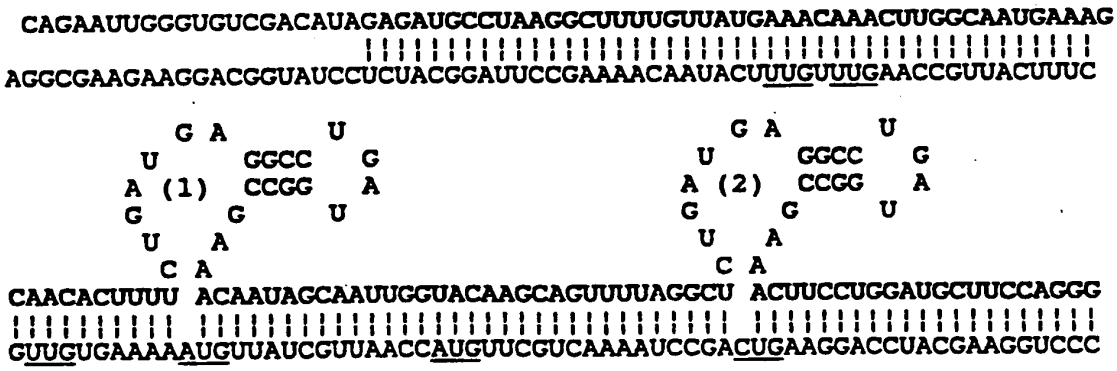

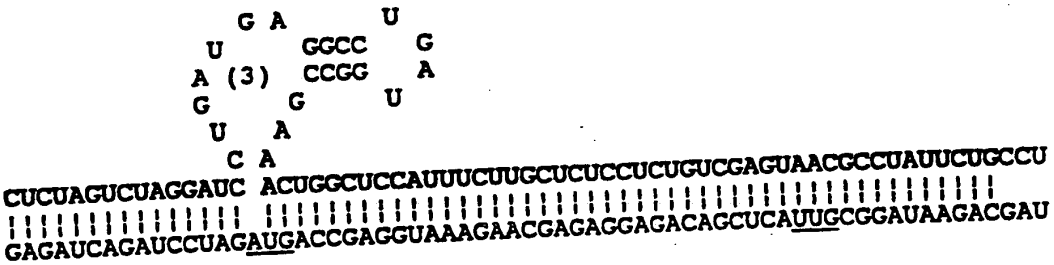

And the genomic organization of the rev(-) antisense-(mono)ribozyme clone, pXE-br(2):

ANTISENSE-(MONO-, BI- or TRI-)RIBOZYME HIV-1 PROVIRAL CLONES

To guarantee at least one cleavage would occur to the sense tat mRNA even when there are mutations, multiple ribozymes targeted to different areas were arranged into the antisense sequences. Besides the "GUC" chosen, as mentioned above, two "GUA" triplets also were chosen as ribozyme targets. Potentially, four "GUU" and another "GUA" can also be chosen as targets if desired. The three sites chosen with their incorporated 22-base ribozyme catalytic domains are as follows. At the site of incorporation, the ribozyme sequence replaces a "G", or "U" of the antisense RNA.

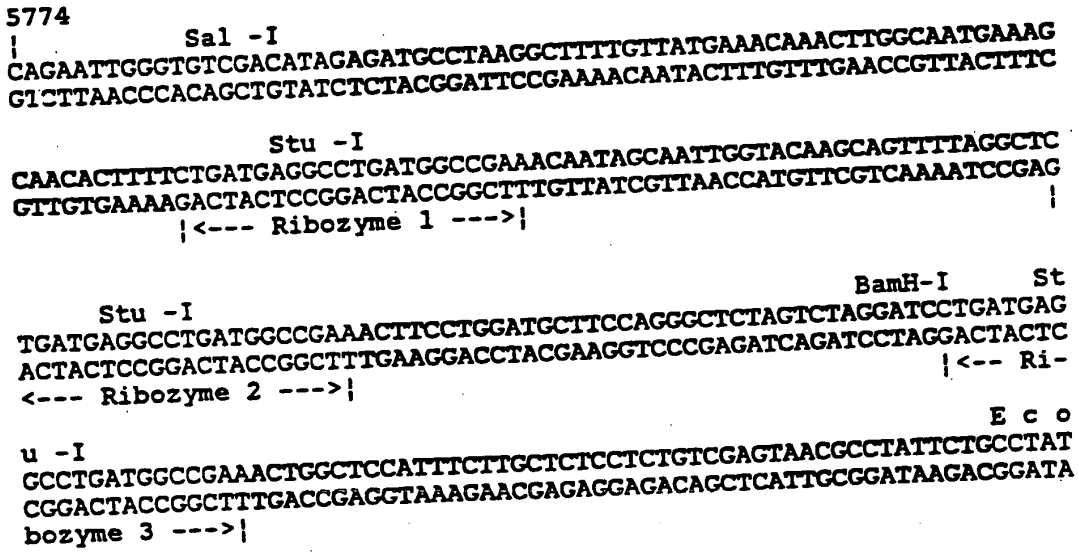

AUGGCAGGAAGAAGCGGA-3'

ACAGCUGUGGGUUAAGAC-5'

Upper Line: Antisense RNA sequence, written 5'-->3', with 3 ribozyme catalytic domains incorporated.

Lower line: Natural mRNA sequence, written 3'-->5', with all potential ribozyme cleavage sites underlined.

Below, the antisense strand is written into DNA with complementary sequences. Note the ribozyme sequences. The first base pair corresponds to the wild type nt 5774 and the last 5986.

Members of ribozymes incorporated	/	1	2	3	1,2	1,3	2,3	1,2,3
Total ribozyme copy incorporated	0	1	1	1	2	2	2	3
Size of PCR fragments (bp)	201	222	222	222	243	243	243	264

Thermal cycling was for 50 cycles, each consisting of 94 degree C for 20 seconds, 60 degree C for 30 seconds and 74 degree C for 30 seconds.

All three Pribo primers were present in the PCR system. Each Pribo primer, by chance, inserted its sequence (carrying one member of the ribozymes) into the PCR amplification product, which was a mixture of antisense-ribozyme fragments with 0, 1, 2 or 3 ribozyme domains incorporated in a random fashion.

The synthesized fragment, using primer Trev(+) 5795, SEQ ID NO:1, with all three members of ribozyme incorporated is 264-bp:

PCR fragments with any two ribozymes incorporated would be 243-bp long. Those with any one ribozyme would be 222-bp, and those without ribozyme would be 201-bp.

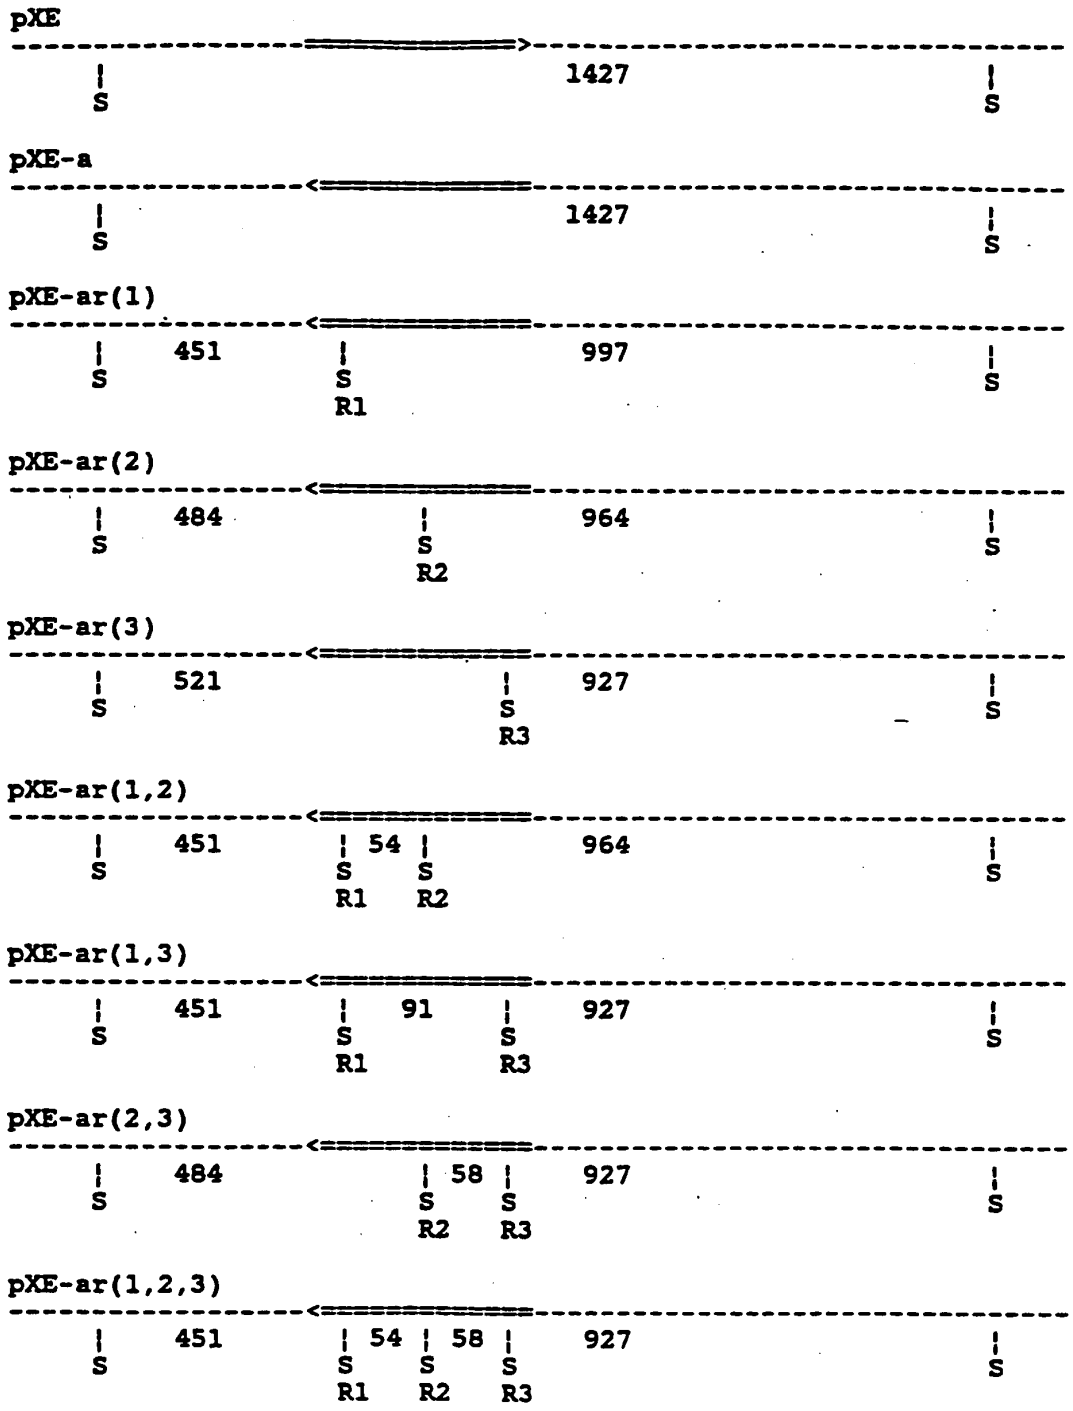

PCR products, together with plasmid pXE, were digested with SalI plus EcoNI then self-ligated. The ligations were used to transform competent HB101 cells as detailed earlier.

Alternatively, ribozyme domains are implanted one by one. Another alternative is to isolate the right DNA fragment after each PCR reaction, then use it as template for next round of PCR implantation/amplification.

Miniplasmids were screened by StuI digestion for various antisense-ribozyme clones. There are two StuI sites (nt 5404 and 6831) in the provirus sequences of the HXB2, producing a fragment of 1427 bps with the area to be turned antisense lying in between. This StuI fragment remains the same in antisense clones pXE-a and pXE-b. Since every ribozyme catalytic domain contains one StuI site, the implantation of one, two or three ribozymes will, respectively, interrupt the StuI fragment into two, three or four bands whose exact sizes can be calculated as indicated in the following graphics, where

S = StuI sit ,
R1 = Ribozyme 1,
R2 = Ribozyme 2,
R3 = Ribozyme 3.

Clones of pXE-br series are exactly the same as those of pXE-ar f r StuI digestion.

pX as well as pXE has two other StuI sites in the plasmid vector sequence. The internal proviral band (1427 bps) is the smallest. Moreover, the addition of the StuI sites in the ribozyme sequences results in even smaller bands. So the screening of the miniplasmids using StuI digestion proved to be handy and precise. Note the incorporation of one ribozyme has effectively inserted 21 bps into the sequence (plus 22-bp ribozyme, minus 1 bp the ribozyme replaced), causing the sum of base pairs with antisense-ribozyme clones to be larger than 1427.

Restriction Digestion Patterns of Molecular HIV-1 (HXB2) Full-Length Clones and Major Subclones.

If the exact size of a particular fragment (band) is known, it is indicated by exact number in bp (base pairs); If the exact size is not known, the estimated size will be indicated by kb (kilobase). Bold-type indicates major clones or bands of interest for the particular restriction enzyme digestion.

484bp					-	-					

Note: The only antisense-ribozyme clones listed in all restriction digestion charts are pXE-ar(2) and pXE-br(2), shown as Ear and Ebr.

The "antisense-ribozyme HIV-1 proviral clones" pXE-ar series [constructed with Trev(+) primer] and pXE-br series [constructed with Trev(-) primer] are transfected into antisense/ribozyme virus producer cell line (see below). The virus particles produced (antisense-ribozyme viruses, ARV) are very powerful in inhibiting the replication of the natural HIV-1 viruses. In addition to the blockage activity as that of antisense viruses (ASV), the ARV also possess the ability to cleave the bound tat mRNA at 1 to 3 loci, rendering tat mRNA impossible to be translated into TAT protein.

Example 4: PREPARATION OF HIV-1 PLASMID CLONE FOR ANTISENSE/ RIBOZYME PROVIRUS CONSTRUCTIONS

The construction of antisense/ribozyme HIV-1 proviral clones began with pX. pNL was employed for some special purposes.

Restricti n site rearrangements became necessary after the area t be turned antisense was chosen and the restricti n sites to be used were selected. Before the HIV-1 antisense/ribozyme proviral clones could be constructed with precision and convenience, it was necessary to obtain pXE. As discussed above, pXE contains a unique SalI site and a unique EcoNI site. The DNA sequence between these two unique sites can be replaced conveniently and precisely by antisense/ribozyme fragments, with the replacement products becoming antisense/ribozyme proviral clones.

Restriction mapping shows that there are three EcoNI sites in pX, yielding three bands of about 11.5, 3.8 and 1.7 kb respectively (see Figure 2). Since it was necessary that the EcoNI site at nt 5966 be unique for convenient and precise antisense/ribozyme clone construction, the other two EcoNI sites were removed from the plasmid. The product f having the other two EcoNI sites removed is pXE.

pX contains another EcoNI site at nt 7631 in the proviral sequence (the corresponding site is also present in pNL). The third EcoNI site in pX is about 1.8 kb beyond the 3'-LTR of the proviral sequences, most likely located in the cellular sequence flanking the provirus. The EcoNI site outside the proviral sequence can be deleted by any means without having to worry about any adverse effect. The nt7631 EcoNI site, however, must be removed in a way that preserves the gene in which it resides.

The plasmid preparation strategy, in order to obtain pXE, was to protect the nt 5966 EcoNI site by removing the NdeI fragment (nt 5121-6402 containing the 5966 EcoNI site) from pX. The resultant clone (pX-N) was then subjected to point-mutation of nt 7631 EcoNI by recombinant PCR, followed by DNA polymerase filling-in to erase the EcoNI site outside the HIV-1 sequence. The resultant EcoNI-free subclone, pX-N-E, was reinstalled with the 5121-6402 NdeI fragment. The reestablished full-length proviral clone with the unique EcoNI site at nt 5966, pXE, was used as wild type HIV-1 plasmid and as parental plasmid for constructing all antisense/ribozyme HIV-1 proviral clones.

Similar r arrangements for r striction endonuclease sites are als made to pSE (HIV-2), pK102 (SIV) and p239F (SIV) f r the precision and convenience in constructing antisense/ribozyme proviral clones.

This Example explains in detail the steps taken in preparing pXE, the restriction-site-rearranged HIV-1 wild type plasmid clone which has been used directly for the construction of HIV-1 antisense/ribozyme proviral clones.

REMOVAL OF ECONI SITE AT NT 5966 FROM PX

(1) pX was digested with NdeI (CA¦TATG) which occurs in HIV-1 sequence only at position 5121 and 6402, between which lies the HIV-1 EcoNI site at position 5966. Also in between is the unique SalI site at nt 5785.

pX, 500 ug/ml		5 µl
Reaction buffer, 10x		5 µl
Tris-acetate, pH 7.9	20 mM	
Magnesium acetate	10 mM	
Potassium acetate	50 mM	
DTT	1 mM	
Nde I, 20 u/µl, NEB		1 µl
Double distilled water		39 µl
		50 µl

Incubation was in 37°C for 1 hours.

(2) Ten microliter of the digest was run on agarose gel to ensure that the digestion was satisfactory. NdeI cuts pX twice, yielding two bands of 1281 bp and 16 kb respectively. The digest was heat-inactivated at 65°C for 10 minutes and used directly for ligation:

Above digest, undiluted	4 µl
Ligase reaction buffer, 5x	4 µl
T4 DNA ligase, 1 u/µl, BRL	1 µl
Double distilled water	11 µl
	20 µl

(3) 20 µl of comp tent E. coli c 11 strain HB101 was transfected with 1 µl of 10-fold dilution of the ligation according to the instruction of the manufacturer (BRL) of the competent cells with minor modifications as necessary. After incubating the LBamp agar plate in 37°C overnight, single colonies were picked into 2 ml LB medium supplemented with ampicillin in the final concentration of 50 ug/ml (LBamp). The bacterial cultures were placed in 37°C shaker-incubator overnight.

(4) The bacteria were harvested and miniplasmid DNA extracted according to Sambrook, Fritsch and Maniatis (Molecular Cloning, a laboratory manual, second edition, Cold Spring Harbor Laboratory Press, 1989) with minor modifications as necessary.

(5) Miniplasmids were digested with BglII. pX was also digested and used as control.

Miniplasmid DNA,		3 µl
Reaction buffer, 10x		3 µl
Tris-HCl, pH 7.9	50 mM	
MgCl2	10 mM	
NaCl	100 mM	
Dithiothreitol	1 mM	
BglII, 8u/µl		0.2 µl
Double distilled water		23.8 µl
		30.0 µl

Incubation was at 37°C for at least 3 hours.

For a cleaner agarose gel picture, ribonuclease A (RNase A, Sigma Chemicals) is regularly included at a final concentration of 50 ug/ml in the restriction enzyme digestion system for miniplasmids to destroy the contaminating RNAs. The resultant pictures were much better than restriction digestion without the RNase addition.

Compared to pX parental clone, the subclone with NdeI fragment deleted, pX-N, has one of the Bgl-II fragment (between positions 2095 and 7040) reduced from 4945 bp to a smaller fragment of 3663 bp.

627bp	-	-	-	-	-	-	-	-	-	-	553bp
-	-	-	-	-	-	-	-	-			

Note: BglII and HindIII are routinely used in the construction procedures for HIV-1 plasmid clones. The enzymes are used either to do the first screening of miniplasmids or to further check the correctness of general structure of all HIV-1 plasmid clones. These digestion patterns should be referred to where a BglII or HindIII digestion is discussed.

(6) The deletion subclone pX-N had only two EcoNI sites both of which were to be removed. One was at nt 7631 while the other was about 1.8 kb beyond 3'-LTR of the HIV-1 sequence, most likely within the flanking cellular sequence. Digestion of pX-N with EcoNI yielded only two bands, about 12.0 and 3.8 kb respectively.

Restriction digestion patterns of molecular HIV-1 (HXB2) full-length clones and major subclones.

If the exact size of a particular fragment (band) is known, the xact number in bp (base pairs) is indicated; if the exact size is not known, the estimated size is indicated by kb (kilobase). Bold-type is used for major clones or bands of interest for the particular restriction enzyme

digestion.

Note: This digestion pattern should be referred to while reading the text, especially in this Example at an EcoNI digestion. This Example fully details manipulations taken to achieve a wild type HIV-1 plasmid clone with unique EcoNI site at proviral position nt 5966 (pXE). The purpose of constructing pXE is to facilitate the subsequent construction steps for antisense/ribozyme proviral clones. * not cut by EcoNI

POINT-MUTATION OF ECONI SITE AT NT 7631 BY PCR

(7) To erase the EcoNI site at nt 7631, a point mutation was made t change the nt 7633 "T" to a "G", without altering the encoded envelope protein sequence, since the original codon CCT and the changed codon CCG both encode for the same amino acid proline. (orig nt = original nucleotides; orig pt = original protein; chge to =change to; same pt = same protein; B primer = Bridging primer)

```
Orig nt: GAG TCC GAG ATC TTC AGA CCT GGA GGA GGA GAT ATG AGG GAC
Orig pt:  E   S   E   I   F   R   P   G   G   G   D   M   R   D

EcoNI:                           CCT NNN NNA GG

Chge to: GAG TCC GAG ATC TTC AGA CCG GGA GGA GGA GAT ATG AGG GAC
Same pt:  E   S   E   I   F   R   P   G   G   G   D   M   R   D

B primer:    CC GAG ATC TTC AGA CCG GGA GGA GGA GAT ATG AGG G

EcoNI removed:                   CCG NNN NNA GG
```

The point-mutation and the EcoNI recognition site elimination were accomplished by a special PCR protocol of the subject invention, bridging PCR. Bridging PCR usually involves <u>three</u> (or more) primers instead of two in the traditional PCR system. For the elimination of the nt 7631 EcoNI site, the three primers used were as follows:

5'primer: EcoRI-down 4623

The bridging PCR r action system consisted of:

pX-N, EcoNI digest, about 50 ng/µl		2 µl
Reaction buffer, 10x		5 µl
Tris-HCl, pH8.3	500 mM	
KCl	500 mM	
MgCl2	20 mM	
Gelatine	0.05 %	
dNTP, 2.5 mM each		3 µl
5'primer, 4623-4640 60 ug/ml		2 µl
3'primer, 8670-8642 60 ug/ml		2 µl
"B"primer, 7617-7652 6 ug/ml		2 µl
AmpliTaq DNA polymerase, 5 u/µl (from Perkin Elmer Cetus)		0.2 µl
Double distilled water		33.8 µl
		50.0 µl

The sample with proper controls was run on a DNA Thermal Cycler (Perkin Elmer Cetus) for 50 cycles each consisting of 94°C for 20 seconds, 50°C for 20 seconds and 74°C for 120 seconds. 10 µl of the PCR product was run on agarose gel (NuSieve 3:1, FMC). The correct size of the PCR product should be 2766 base pairs, which was confirmed.

To establish whether the point mutation had been made, PCR products were digested with EcoNI. PCR product from reaction using undigested pX-N template, 5' and 3' (without bridging) primers, was cut into two bands of 1731 and 1035 bps. The bridging PCR product amplified with the system described above was not cut, indicating that the EcoNI site had been eliminated.

(8) The bridging PCR product was digested with EcoRI and BamHI simultaneously and the EcoRI-BamHI fragment of 2546 bp was used to replace the corresponding fragment of pX-N.

The bridging PCR product was extracted once with phenol-chloroform-isoamyl alcohol (25:24:1), mixed with plasmid DNA of pX-N and digested with both restriction enzymes EcoRI and BamHI:

"Bridging" PCR product, extracted		5 µl
pX-N, about 500 ug/ml		2 µl
Reaction buffer, 10x		5 µl
Tris-HCl, pH 8.0	20 mM	
MgCl2	10 mM	
NaCL	100 mM	
EcoRI, 10 u/µl, BRL		1 µl
BamHI, 10 u/µl, BRL		1 µl
Double distilled water		36 µl
		50 µl

Incubation was at 37°C for at least 3 hours.

Ten µl of the digest was run on agarose gel to make sure that the digestion had been satisfactory. The digest was heat-inactivated at 65°C for 10 minutes and used directly for ligation:

Above digest, undiluted	4 µl
Ligase reaction buffer, 5x	4 µl
T4 DNA ligase, 1 u/µl, BRL	1 µl
Double distilled water	11 µl
	20 µl

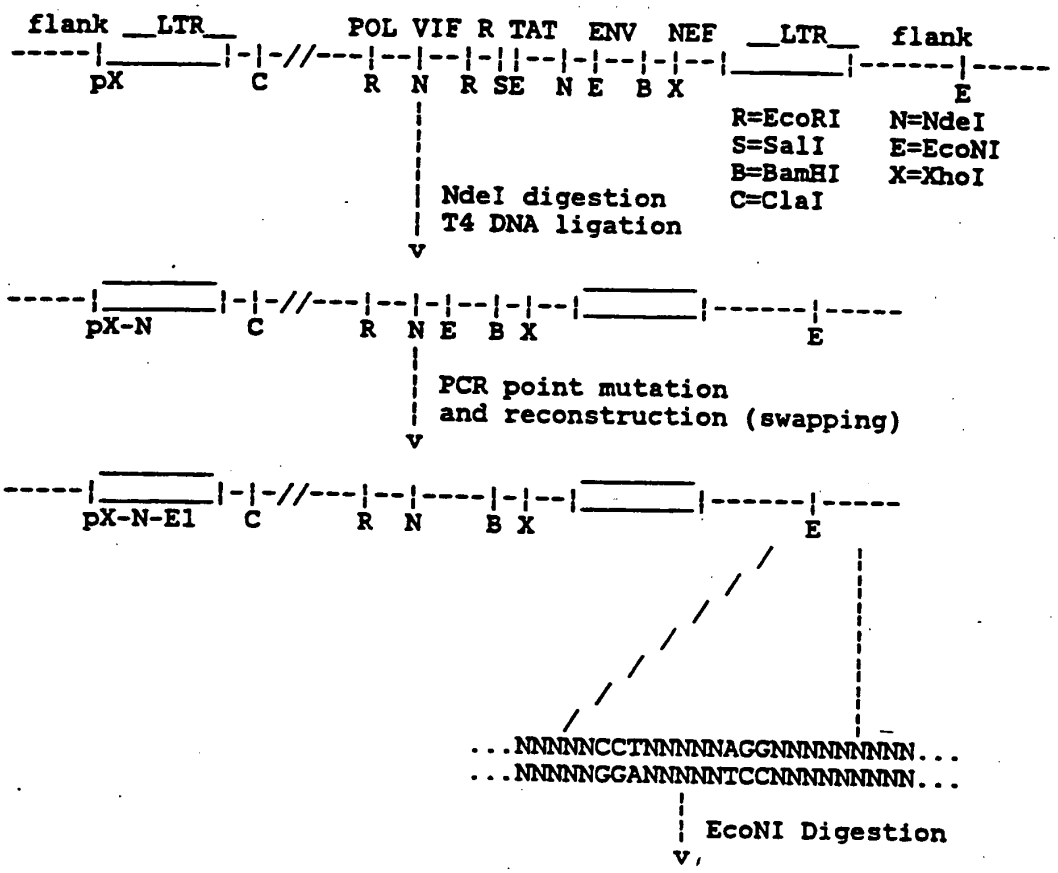

Incubation was at 15°C for at least 3 hours.

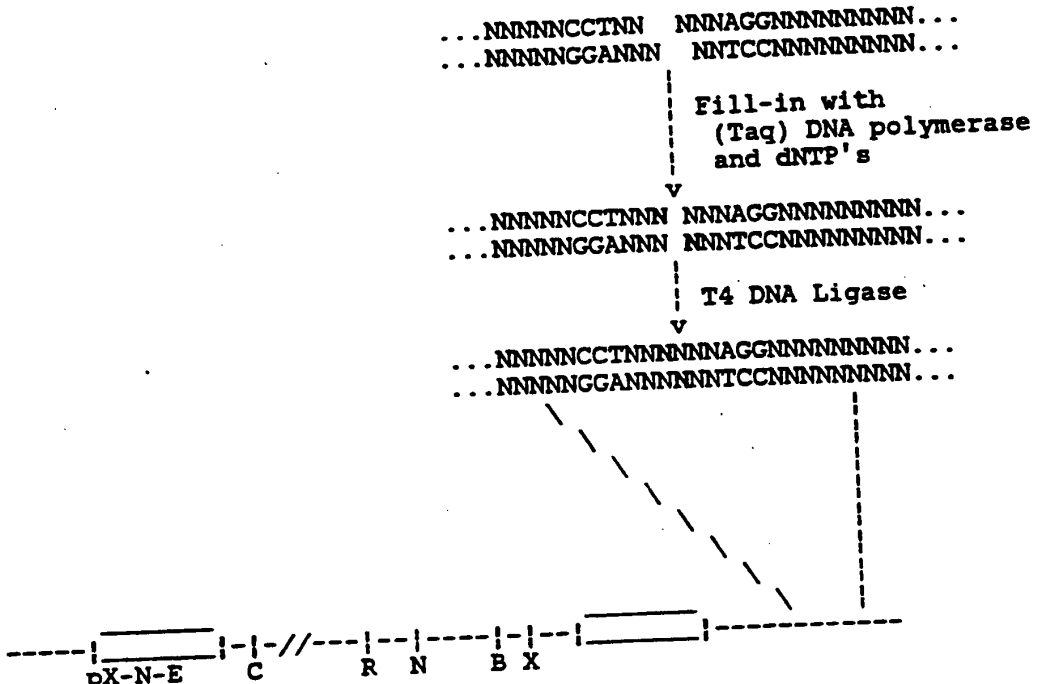

One microliter of the 10-fold dilution of the ligation was used to transform 20 µl of competent HB101 cells. Colonies were picked and miniplasmids were extracted and digested by BglII as well as EcoNI. Successful recombinant clones (pX-N-E1) were cut only once by EcoNI instead of twice for pX-N; while the BglII digestion pattern of pX-N-E1 was the same as that for pX-N. In fact, pX-N-E1 had the same structure as pX-N except the nt 7633 "T" is changed to a "G". (see the restriction digestion patterns).

ELIMINATION OF OUTSIDE ECONI SITE BY POLYMERASE "FILL-IN"

(9) To abolish the remaining EcoNI site outside of the proviral sequence, pX-N-E1 (5 µg) was cut with EcoNI. The digest was purified by

PCI extraction, ethanol precipitation and was resuspended in 50 µl of 1x TaqI DNA polymerase reaction buffer (diluted from 10x buffer of Perkin Elmer Cetus) with 50 uM of each dNTP and 1.0 unit of TaqI DNA polymerase. The mixture was placed in 70°C for 1 minute ("fill-in" took place here) then subjected to PCI extraction (phenol-chloroform-isoamyl alcohol (25:24:1)). 4 µl of the mixture was used for ligation in a 20 µl system as in paragraph (8) above. One microliter of the 10-fold dilution of the ligation was used to transform 20 µl of competent DM1 cells which are dam methylase negative (GIBCO BRL). Colonies were picked and miniplasmids were extracted and digested by HindIII as well as EcoNI. Successful recombinant clones (pX-N-E) were not cut by EcoNI, but showed the same HindIII digestion pattern as pX-N and pX-N-E1 (see the restriction digestion patterns). In fact, pX-N-E has the same structure as pX-N except the nt 7633 "T" is changed to "G" and the outside EcoNI is eliminated.

EcoNI Digestion

EcoNI cuts the sequence CCT(N)5AGG. When there are six (6) bases in between CTT and AGG, i.e., CCT(N)6AGG, EcoNI will not cut any more.

REINSTALLATION OF THE NDEI FRAGMENT

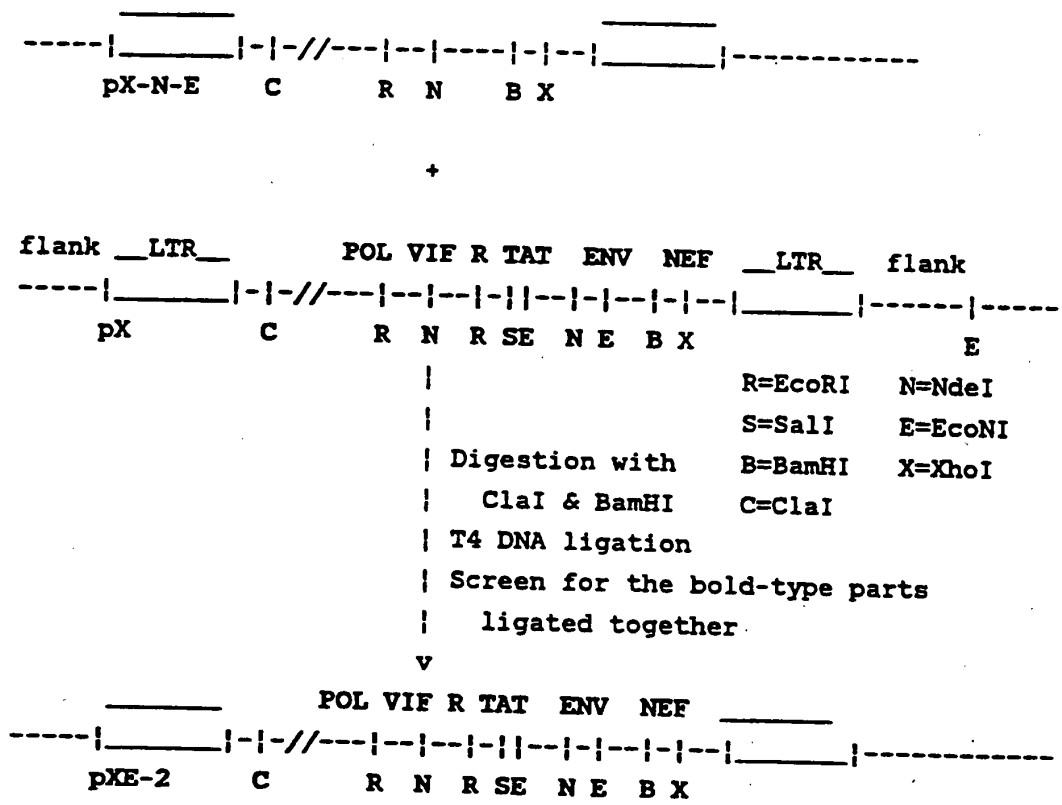

Because of the limited availability of convenient restriction sites, the re-installation of the NdeI fragment took two-steps: first to reconstruct full-length plasmid (pX-E2), then to mutate the EcoNI site at nt 7631 again.

(10) pX-N-E and parental pX (both prepared from transformed DM1 cells) were digested simultaneously with ClaI (nt 829) and BamHI (nt 8474). The digest mixture was self-ligated and used to transform competent HB101 E. Coli cells.

(11) Miniplasmids were screened by BglII and HindIII digestion. Those with the same digestion patterns as pX would be the full-length clones.

(12) The full-length clones were further checked by digesting with

EcoNI, and the clone cut twice and yielding a band of 1665 bps was chosen and named as pXE-2. pXE-2 is the same wild type clone as pX but with the outside EcoNI site removed.

(13) Another bridging PCR, in order to mutate the EcoNI site at nt 7631 which had been reinstated into pXE-2.

It becomes clear that, even with an intact template, the bridging primer would be able to insert its sequence into some of the amplified fragments. To confirm the successful implantation of the "T --> G" (i.e., CCTNNNNNAGG --> CCGNNNNNAGG) point mutation at nt 7633, the PCR products were digested with EcoNI. Control with only 5' and 3' primers the whole fragment was 2932 bps. The product was cut into three bands of 232, 1665 and 1035 bps respectively.

For the PCR with three primers, the undigested product was a mixture containing two bands of 2932 and 1053 respectively. When cut with Ec NI, four bands appeared. Besides the 1665, 1053+1035, and 232 bp bands, another band appeared at 2.7 kb, due to considerable amount of the product carrying the point mutation at nt 7633 resulting in the elimination of EcoNI site at nt 7631.

The PCR product with 2.7 kb band was digested along with pXE-2 plasmid by restriction enzymes SalI and BamHI. The digest was self-ligated. The ligation was used to transform competent HB101 cells. Miniplasmids were screened with HindIII then with EcoNI. The clone with nt 7631 EcoNI site mutated, pXE, showed the same HindIII digestion pattern as that of pX or pXE-2, but was cut only once by EcoNI compared to twice for pXE-2 and three times for pX.

pXE was used later for constructing antisense molecular clones. pXE can also be used as wild type control just as pX.

(**) The abolishment of the two extra EcoNI restriction sites can be done in an alternative way. The starting pX plasmid prepared from DM1 competent cells can be digested simultaneously or consecutively with both BclI (nt 2428) and BamHI (nt 8474) then self-ligated.

(Note: BclI and BamHI produce compatible cohesive ends that can be ligated to each other. But the ligation product cannot be recut by either enzyme. Compatible cohesive ends unable to be recut after ligation also occur between SalI and XhoI, see gene-expression vector construction below. BclI recognizes TGATCA and cuts between "T" and "G", but this sequence will not be cut by BclI when the middle "A" is methylated by Dam methylase. DM-1 E. coli cells are Dam methylase negative. DNA prepared from DM-1 cells are not methylated and therefore can be cut by BclI.)

The plasmid clone with BclI - BamHI fragment deleted ("pX-BB") has both proviral EcoNI sites removed. pX-BB can be cut with EcoNI, treated

with TaqI polymerase, self-ligated and used to transf rm DM1 competent cells. This results in the abolishment of the outside EcoNI site. This clone ("pX-BB-Eo") together with pX can be cleaved simultaneously with ClaI (nt 829, ClaI is also Dam methylation sensitive and demands DM-1 cell prepared DNA for effective cleavage) and XhoI (nt 8896), self-ligated, and used to transform competent cells. The full-length clone with only two proviral EcoNI sites (pX-E2) can be used for sequence swapping with "bridging PCR" product between SalI and BamHI as described in Step (13). The final clone with only one EcoNI site at nt 5966 is pXE.

CONSTRUCTION OF FULL-LENGTH ANTISENSE/RIBOZYME MOLECULAR CLONES

(14) PCR reactions were performed using pX or other appropriate plasmids as templates and Tvpr/Trev or/and other primers as depicted previously. The PCR product was checked by running 10 µl on agarose gel. The fragments were shown to be of expected sizes and/or of expected restriction digestion patterns.

(15) Each of the PCR products together with plasmid pXE were digested with SalI and EcoNI, simultaneously.

Restriction Digestion Patterns of Molecular HIV-1 (HXB2) Full-Length Clones and Major Subclones.

If the exact size of a particular fragment (band) is known, it is indicated by exact number in bp (base pairs); if the exact size is not known, the estimated size is indicated by kb (kilobase). Bold-type indicates major clones or bands of interest for the particular restriction enzyme digestion.

Example 5: CONSTRUCTION F TAT-EXPRESSION VECTORS USING HIV-1 MOLECULAR CLONES

Recombinant PCR is employed to construct tat-expression clone with major HIV-1 genes truncated. The advantage of PCR recombination is that it is easy to construct the molecular clone(s) with precision. The steps used are as follows:

(1) The tat-expression clone, as mentioned above, has the gag, pol reading frames truncated but has vpr, tat, rev and env intact. Examining pX, the sequences at the beginning of the gag open reading frame and the sequences starting from position 5320 (in the mid-frame of vif, before splice junction site 5388/5389) are as follow:

```
                                                    825       835     942
          789                                        |   Cla -I|       |
          |                                          |    ATCGAT       |

```

SEQ ID NO:17

TTAGATCGAT GATAGCACAC AAGTAGACCC TG

32

(3) Primer HTX 835-5320 was used to couple with another primer, Rvpr 5794-5767, in the PCR reaction with pNL as the template.

Rvpr 5794-5767 CTATGTCGACACCCAATTCTGAAATGG

SEQ ID NO:18

CTATGTCGAC ACCCAATTCT GAAATGG 27

This is a negative-strand primer specially designed to restore the "perfect" vpr reading frame by deleting a "T" at 5770 of HXB2. Compare this primer with the original sequences in HXB2 and NL4-3:

HXB2 SEQ	5767	CCATTTTCAGAATTGGGTGTCGACATAG	5794	(positive)
		GGTAAAAGTCTTAACCCACAGCTGTATC		(negative)
Rvpr SEQ	5767	GGT-AAAGTCTTAACCCACAGCTGTATC	5794	(negative)
NL43 SEQ	5768	CCATTTCAGAATTGGGTGTCGACATAG	5794	(positive)
		GGTAAAGTCTTAACCCACAGCTGTATC		(negative)

It becomes clear that primer Rvpr is actually made of sequences of pNL which preserve intact and functional vpr gene. As discussed previously, the vpr gene has been truncated and is functionless with HXB2, the plasmid clone of which, pX, has been used as parental structure for all the antisense/ribozyme proviral clones. Restoration of vpr function in the gene expression vector benefits the antisense/ribozyme viruses' ability to replicate by providing the antisense/ribozyme virus producer cell lines with the "weak transcriptional activator" (see Fig. 2). That is, the use of pNL sequence is to restore vpr function with the gene-expression vector. The inclusion of the ClaI restriction site is to facilitate the subsequent cloning of the gene-expression vector.

pNL, 1 ug/ml		1 µl
Reaction buffer, 10x		5 µl
Tris-HCl, pH 8.3	500 mM	
KCl	500 mM	
MgCl2	20 mM	
Gelatine	0.05 %	
dNTPs, 2.5 mM each		3 µl
HTX 835-5320, 60 ug/ml		2 µl
Rvpr 5794-5767, 60 ug/ml		2 µl
AmpliTaq DNA polymerase, 5 u/µl		0.2 µl
Double distilled water		36.8 µl
		50.0 µl

Fifty cycles of thermal cycling were done, each consisting of 94°C for 20 seconds, 50°C for 20 seconds and 74°C for 2 minutes.

The PCR product was 485 bps total. The main part of it was a 474-bp fragment from nt 5320 (pNL nt 5321) to nt 5794 (same for both clones). This 474-bp fragment is of NL4-3 origin, which is 1 bp shorter than and 26 bps different from the corresponding fragment of HXB2. The PCR product further included at its 5' end 11 bps of HXB2 origin (nt 825-835) where the unique Cla-I site is located. The following shows the actual sequences of the PCR product.

The first coding region at the beginning of the fragment where only 3 amino acid residues are shown is the carboxyl terminus of the truncated GAG protein. The second coding region starting at nt 250 is VPR which continues beyond this fragment as shown in SEQ ID NO:20.

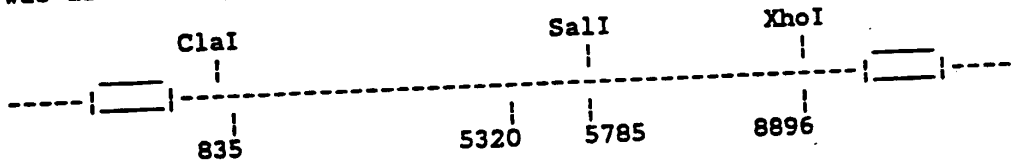

(4) The PCR product together with full-length pX (prepared from dam methylase negative DM-1 competent cells from GIBCO BRL) were cleaved with Cla-I and Sal-I simultaneously. The digest was religated with T4 DNA ligase and the ligation was used to transformed HB101 as well as DM-1 cells. Miniplasmids were screened with restriction enzyme digestion,

looking for the cl ne where the natural ClaI - SalI fragment (4955 bps) had been replaced by the PCR ClaI - SalI fragment (470 bps). 4484 bps had been deleted. The miniplasmids were cut with BglII. The right deletion clone yielded a 2083 bp fragment while the two wild type fragments of 1622 bp (nt 473-2095) and 4945 bp (nt 2095-7040) disappeared. Mathematically, 6567 bp (nt 473-7040) minus 4484 bp (nt 836-5319) equals 2083 bp.

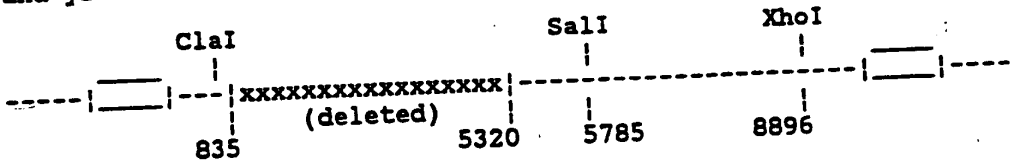

PCR made fragment (SEQ ID NO:19, with the portion truncated)

was used to replace the ClaI-SalI fragment of the wild type pX,

and yielded the recombinant truncation clone pX-CS.

Restriction Digestion Patterns of Molecular HIV-1 (HXB2) Full-Length Clones and Major Subclones.

If the exact size of a particular fragment (band) is known, it will be indicated by exact number in bp (base pairs); If the exact size is not known, the estimated size will be indicated by kb (kilobase). Bold-type indicates major clones or bands of interest for the particular restriction enzyme digestion.

In this recombinant truncation clone, "pX-CS", the gag gene is truncated to 15 amino acids only; a "perfect" vpr gene has been reinstated (by replacing HXB2 vpr gene with NL4-3 vpr gene); while most of the gag gene, all of pol gene, and the 5' portion of the vif gene have

been deleted. Preserved are the major 5' splice donor site 742/743, splice junction sites 5388/5389, 5462/5463, 5776/5777, 5975/5976, 6044/6045, and 8377/8378. Tat, rev, vpr and env genes are intact. The nef open reading frame (orf) is also intact, but it is interrupted by the insertion of a neo(r) cassette into the unique XhoI site at nt 8896.

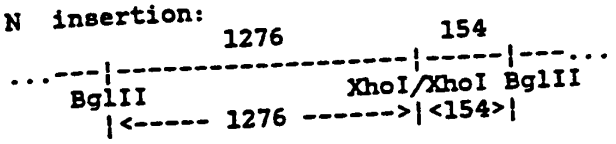

(5) The neomycin resistance cartridge from pMClneoPolyA (Stratagene) is inserted into the XhoI site (8896) of pX-CS. The cartridge is 1146 bp long between XhoI (nt 451 of pMClneoPolyA) and SalI (nt 1597 of pMClneoPolyA), containing the neo(r) gene from Tn5, the Herpes Simplex thymidine kinase promoter and the enhancer sequence from polyoma virus Py F441. pX-CS was digested with XhoI, and pMClneoPolyA was digested with XhoI and SalI. After killing the restriction enzymes' activities by heating the digests at 65°C for 15 minutes, the two digests were mixed together for ligation. SalI and XhoI produce compatible restriction ends capable of ligating to each other, the ligation product of which, however, cannot be cut by either enzyme.

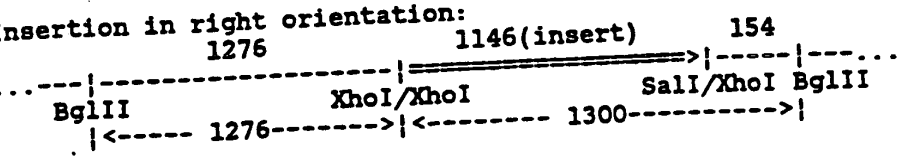

(6) The ligation is then used to transform competent E. Coli HB101 cells. Single colonies were picked into LBamp medium.

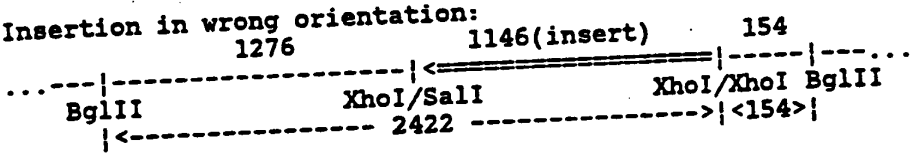

(7) Recombinant miniplasmids are digested with BglII and XhoI simultaneously.

Clones without insertion have, among others, two bands of 1276 bp (BglII 7620 - XhoI 8896) and 154 bp (XhoI 8896 - BglII 9050). Note the GenBank BglII site 8085 is missing from pX.

Clones with insertions have either a 1276 bp band and a 1300 bp band (154 + 1146 = 1300, right orientation), or, a 2422 bp band (1276 + 1146 = 1957, wrong orientation) and a 154 bp band.

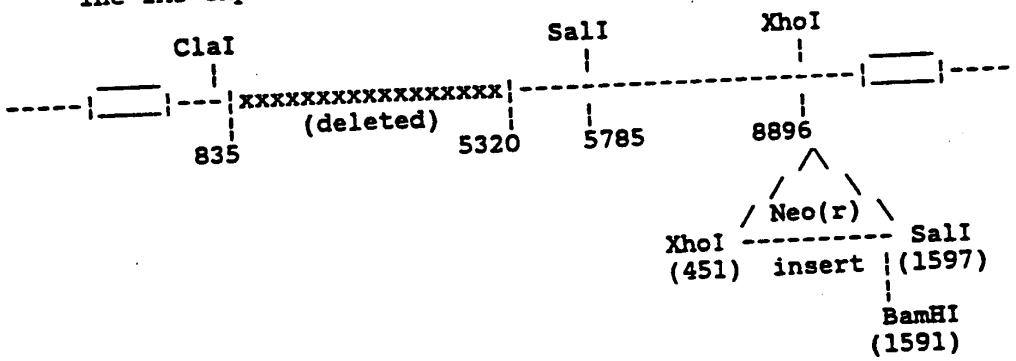

XhoI/XhoI = XhoI end ligated to XhoI end. The ligation product can be recut by XhoI.

SalI/XhoI = SalI end ligated to XhoI end. The ligation product cannot be cut by either SalI or XhoI.

The clone with 1300 bp band is chosen as HIV-1-tat-expression vector (pX-CSneo). The nef open reading frame has been interrupted by the insertion of a neo(r) cassette.

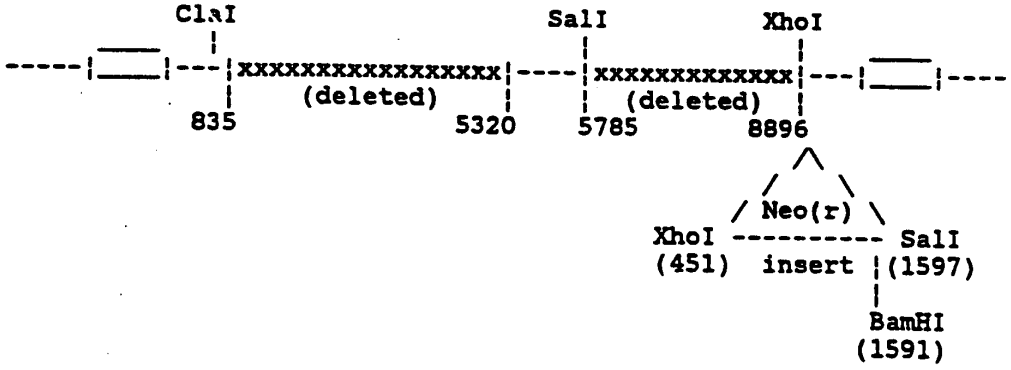

The TAT-expression clone pX-CSneo

The binding together of the neomycin resistance gene and the tat gene assures the entry of both genes into the cells at the same time, transforming the cells into neomycin resistance and tat expression simultaneously. By including antibiotic G418 in the cell culture medium, every surviving cell produces TAT protein, capable of supporting the production of the antisense/ribozyme viruses.

(9) As control, a tat(-) but neomycin(r)(+) clone is constructed from pX-CSneo. pX-CSneo is simultaneously digested with SalI (cut HIV1 nt 5785 only) and XhoI (cuts the ligation junction HIV1 nt 8896-XhoI and pMCneoPolyA nt 452-XhoI, but does not cut the ligation junction between pMCneoPolyA nt 1597-SalI and HIV1 nt 8897-XhoI, the latter junction is not be cut by SalI either). Religation of the fragments is used to transform competent E. Coli HB101. Miniplasmids are screened for the clone with SalI (5785) to XhoI (8896) fragment (3111 bp) deleted. This clone basically carries two HIV-1 LTRs with with the neo(r) gene in between. It is named pX-neo.

The TAT-expression control clone pX-neo

Example 6: CONSTRUCTION OF TAT-EXPRESSION CLONE USING NON-HIV1 VECTOR

The aforementioned truncation tat-expression vectors employ identical promoter/enhancer systems with HIV-1 antisense/ribozyme

proviral clones. Tat-expression vectors using other promotors were also constructed. This is done by inserting the tat coding sequence into one of many gene expression vectors such as SFneo. SFneo contains spleen focus forming virus (SFFV) LTR as the promotor to drive the inserted gene to express protein. SFneo also contains a neomycin resistance gene expression cassette [Neo(r)], enabling the transformed cells to grow in the presence of antibiotic G418. Since the tat and rev coding regions overlap with each other, it was decided that both coding frames be kept intact. It was also decided that the two exons of the coding frame be linked together before being inserted into the expression vector. The two halves of the coding regions are as follows:

Note: The numbers given on right side of the sequences are the original position for the last base of that line. TAT and REV proteins are lined up with their coding nucleotide sequences. Also given are splice donor (sd) and splice accepter (sa) sites, as well as some important restriction sites.

For easy demonstration of the procedures by which the two parts of the genes are linked together, the protein sequences are removed and the complementary DNA sequences are added.

PCR was employed to accomplish the linkage. The PCR protocol us d is "bridging PCR". The protocol was designed to link together at precise positions two segments of originally separated DNA and to amplify the linked sequences with the same PCR reaction in the same tube. A critical feature of "bridging PCR" is to include three (or more) primers in the PCR reaction: two ordinary primers to anneal to either end of the linked fragment, and one (or more) "bridging primer" to span the intended areas

of linking. A "bridging primer" can be either orientation, but amplification may be more efficient if it points to the shorter half of the linked fragment.

For linking together the two exons of tat and rev genes, the three primers are designed as follows.

5'-end primer: HTX 5738, i.e., SEQ ID NO:16

```
     Eco RI
ATAAGAATTCTGCAACAACTGCTG
|------5738-5761------>|
```

"Bridging primer": HTX 6044-8378

```
 Hind-III
CAAGCTTCTCTATCAAAGCAACCCACCTCCCAACCCCGAG
|----6025-6044----->----8378-8397----->|
```

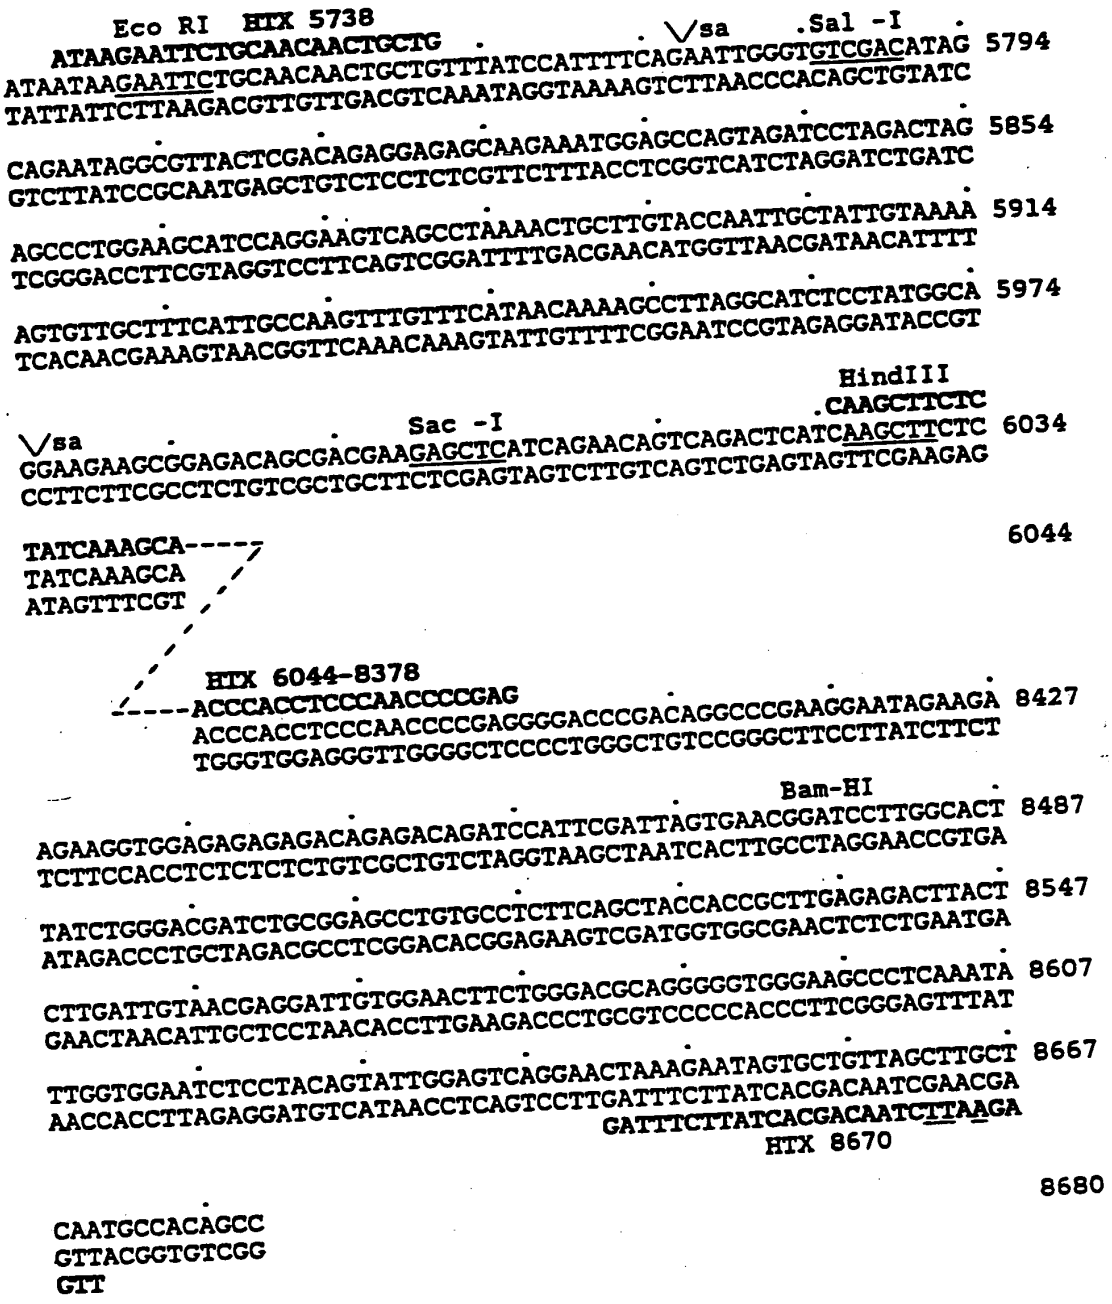

SEQ ID NO:21

CAAGCTTCTC TATCAAAGCA ACCCACCTCC CAACCCCGAG 40

3'-end primer: HTX 8670, i.e., SEQ ID NO:14. The 3 bases underlined has been changed to accommodate an EcoRI site.

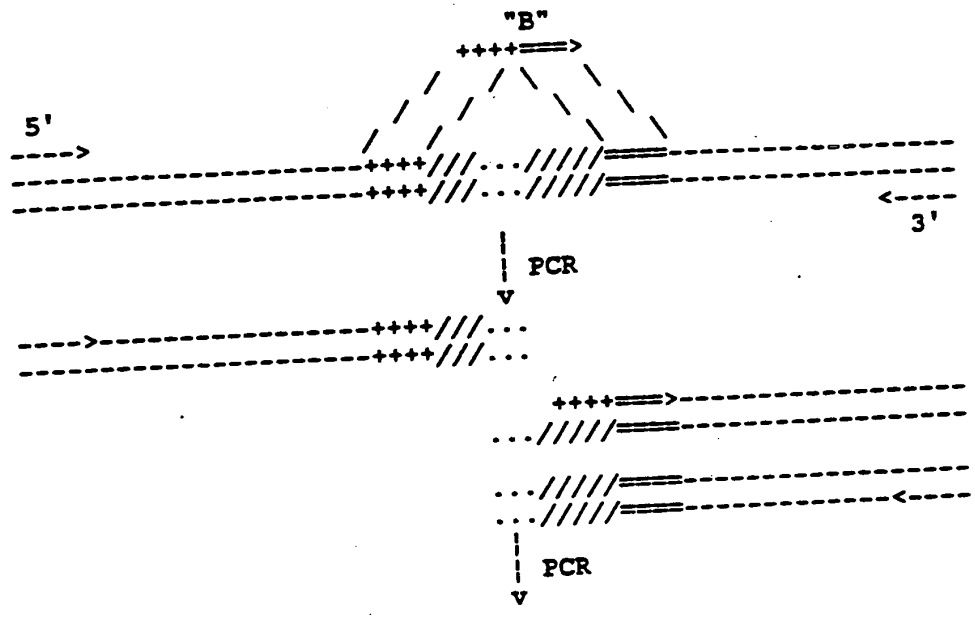

```
     Eco-RI
TTGAGAATTCTAACAGCACTATTCTTTAG
|---------8670-8642-------->|
```

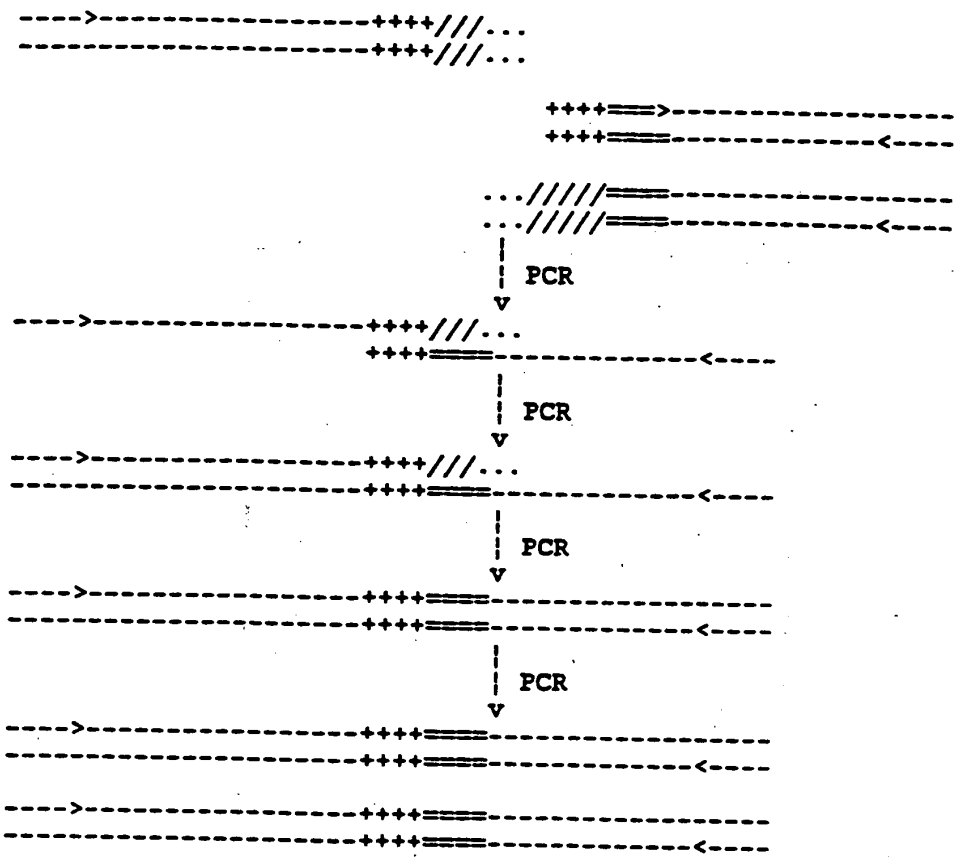

The primers, in bold-type l tters, anneal to the sequenc s at positions:

The "bridging primer" (HTX 6044-8378, 40 mer) was composed of the sequence 6025-6044 (20 mer) and the sequence 8378-8397 (also 20mer), pointing down towards the 3'-end of HIV genome. Although the "bridging primer" also anneals to the negative strand at the positions of 6025-6044, only when it bound to the position 8378-8397 can the polymerization (elongation) be initiated. Therefore the "bridging primer" pairs with the 3'-end primer (8670-8642) to amplify the fragment from 8378 to 8670 plus 20 base pairs corresponding to the positions 6025-6044, totaling 312 base pairs in length. When there are more 3'-end primer than the "bridging primer", more negative strands (initiated by 3'-end primer) than positive ones (initiated by "bridging primer") are amplified. The negative strands would carry at their 3'-ends the complementary sequence to the "bridging primer." The very 3'-end of these single-stranded DNA would anneal to the positive strands at position 6025-6044 of the original templates or to the single-stranded DNA initiated by the 5'-end primer (5738-5761). As soon as the "bridging primer complementary sequence"-initiated DNA elongation reached the positions 5738-5761, the two fragments are physically linked together. From then on the amplification depends only on two primers annealing to either end of the linked fragment. The events are illustrated as follows:

"B" = "Bridging primer", HTX 6044-8378
5' = 5'-end primer, HTX 5738
3' = 3'-end primer, HTX 8670

"Bridging PCR" reaction system:

pX, 1 ug/ml		1 µl
Reaction buffer, 10x		5 µl
Tris-HCl, pH 8.3	500 mM	
KCl	500 mM	
MgCl2	20 mM	
Gelatine	0.05 %	
dNTP's, 2.5 mM each		3 µl
5'-primer, HTX 5738-5761, 60 ug/ml		2 µl
3'-primer, HTX 8670-8642, 60 ug/ml		2 µl
"B"primer, HTX 6044-8378, 6 ug/ml		2 µl
AmpliTaq DNA polymerase, 5 u/µl (from Perkin Elmer Cetus)		0.2 µl
Double distilled water		34.8 µl
		50.0 µl

The thermal cycling setting was 50 cycles, each consisting of 94°C for 20 seconds, 54°C for 20 seconds and 74°C for 60 seconds.

The amplified fragments would have the sequences 5738-6044 (307 bp) and 8378-8670 (293 bp) linked into one piece (600 bp) containing full-length tat and rev sequences in continuation.

The EcoRI fragment (586 bp) of the PCR product is inserted into Eco RI site of SFneo (see Figure 5). The recombinant plasmid are screened with Sal-I enzyme digestion. The plasmid without the insert yield a single band of 7227 bps (SFneo only). Plasmid with inserts show two

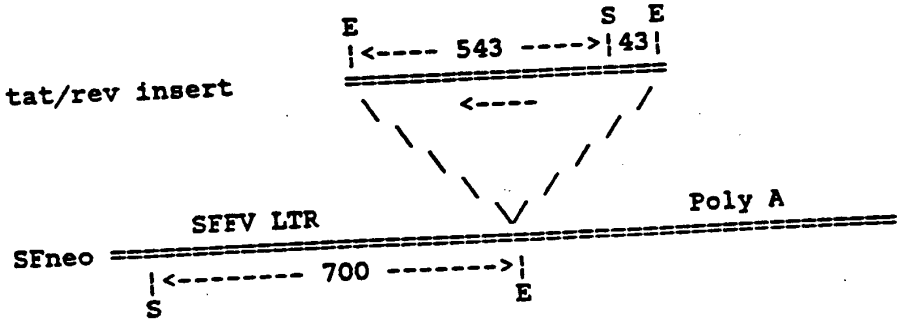

bands, the smaller of which is either 743 bps (insertion in right orientation) or 1247 bps (insertion in wrong orientation). The recombinant plasmid in right orientation, SFneo-t/r(+) (stands for tat/rev positive or sense) is advantageously chosen as the complemental gene expression vector for antisense/ribozyme proviral clones. The one in wrong orientation, "SFneo-t/r(-)"(stands for tat/rev negative or antisense), is used in the experiments of vector-expressed antisense tat-rev RNA inhibition of wild type HIV-1 viruses.

E = EcoRI
S = SalI

Insertion in right orientation [SFneo-t/r(+)]:

Insertion in wrong orientation [SFneo-t/r(-)]:

Example 7: CONSTRUCTION OF TAT-EXPRESSION VECTORS CONTAINING CONTAINING CHEMICALLY SYNTHESIZED TAT ENCODING SEQUENCE

With gene-expression vectors constructed by the above-mentioned protocols, either driven by HIV-1 or another promotor, there exists the

possibility that the antisens RNA transcribed fr m the antisense/ribozyme clones will bind and inactivate the sense tat mRNA from the gene-expression vectors. This potential problem rests on the one-hundred-percent sequence complementation between the tat's in antisense/ribozyme molecular clones and that in the gene expression vectors. If this occurs, there may not be enough TAT protein available for efficient replication of antisense/ribozyme viruses.

Proteins are composed of amino acids which in turn are encoded by nucleotide triplets. The fact that most amino acids (except methionine and tryptophan) are encoded by more than one nucleotide triplet creates the possibility of diversifying nucleotide sequence while keeping the amino acid sequence unchanged for a particular protein.

The following shows one of the diversifications for tat-protein-coding nucleotide sequences. The first line shows the original tat nucleotide sequence (HXB2); the second the amino acid sequence; and the third the diversification of tat nucleotide sequence. Of the 87 codons, all except two (the initiator methionine and the eleventh residue tryptophan) can be altered at at least one base. 8 arginines and 3 leucines can be changed at two bases. The 7 serines can be changed at all three bases. The stop codon too can be changed at two bases. In total, 111 out of 261 (42.5%) nucleotides can be changed, enough to nullify complementation.

Since the expression vectors will also be utilized for the production of antisense-ribozyme viruses (ARV), care has been taken to nullify the potential ribozyme target sites, in order to avoid the binding of diversified tat mRNA by ribozymes expressed by the ARVs.

The oligonucleotides, each with a 15-base overlap with the adjacent oligonucleotide, were linked into the full-length DNA fragment of 285 bps. All the oligonucleotides were mixed together, with the first and the last ones (numbers 1 & 6) added in amounts ten times as much as the others. In the presence of dNTP's and TaqI DNA polymerase, the mixture underwent thermal cycling just as in an ordinary PCR reaction. By priming to each other, the oligonucleotides were linked together and amplified, as shown below:

The full-length fragment to be made:

Chemically synthesized single stranded oligonucleotides, arrows point from 5' to 3':

The reaction product was cleaved with EcoRI and the 273 bp fragment inserted into SFneo at EcoRI site. The recombinant clones were screened with NcoI restriction enzyme digestion. Clones without insertions (SFneo per se) yield two bands of 6024 and 1023 bps respectively. Clones with insertions have three bands which are either 5114, 1363 and 1023 bps [insertion in right orientation, "SFneo-tat(+)"] or 5317, 1160 and 1023 bps [insertion in wrong orientation, "SFneo-tat(-)"]. See Figure 7.

+ Virus particles are produced;
- Virus particles are not produced;
± Virus particles are produced transiently.

* * *

While the present invention has been described in terms of preferred embodiments, it is understood that variations and modifications will occur to those skilled in the art. Therefore, it is intended that the appended claims cover all such equivalent variations which come within the scope of the invention as claimed.

The features disclosed in the foregoing description, in the following claims and/or in the accompanying drawings may, both separately and in any combination thereof, be material for realizing the invention in diverse forms thereof.

WHAT IS CLAIMED IS:

1. An antisense virus comprising:

a viral coat sufficiently duplicative of a naturally occurring virus viral coat to allow the infectivity of said naturally occurring virus, and

nucleic acid including an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding and inactivating mRNA encoded by said gene encoding a transactivating protein.

2. An antisense virus as in Claim 1 wherein said antisense virus is replication defective.

3. An antisense virus as in Claim 1 wherein said nucleic acid includes all of the structural genes of said naturally occurring virus.

4. An antisense virus as in Claim 1 wherein said nucleic acid includes all of the regulatory genes of said naturally occurring virus except said gene encoding a transactivating protein.

5. An antisense virus as in Claim 1 wherein except for said antisense fragment which encodes antisense RNA, said antisense virus is the same as said naturally occurring virus.

6. An antisense virus as in Claim 1 wherein said naturally occurring virus is an animal virus.

7. An antisense virus as in Claim 1 wherein said naturally occurring virus is a DNA virus.

8. An antisense virus as in Claim 1 wherein said naturally occurring virus is an RNA virus.

9. An antis ns virus as in Claim 8 wherein said naturally occurring virus is a retr virus.

10. An antisense virus as in Claim 9 wherein said naturally occurring virus is selected from the group consisting of HIV-1, HIV-2 and SIV.

11. The antisense virus as in Claim 10 wherein said antisense fragment which encodes antisense RNA is a section of a gene selected from the group consisting of tat, rev and vpr, which has been turned antisense.

12. An antisense virus as in Claim 10 wherein said mRNA is an mRNA encoded by a gene selected from the group consisting of tat, rev, and vpr.

13. An antisense virus as in Claim 6 wherein said virus is a human T-lymphotropic virus.

14. An antisense virus as in Claim 6 wherein said virus is hepatitis B virus.

15. An antisense proviral molecular clone including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding and inactivating mRNA encoded by said gene encoding a transactivating protein.

16. A method of synthesizing an antisense proviral molecular clon comprising the steps of:

a) inserting DNA encoding a naturally occurring virus into a vector; and

b) creating an antisense fragment in said DNA by turning antis nse a section of a gene of said DNA, said gene encoding a transactivating protein required for said naturally occurring

virus to replicate, said antisense fragment encoding antisense RNA capable of binding and inactivating mRNA encoded by said gene encoding a transactivating protein.

17. A method as in Claim 16 wherein said vector is a plasmid.

18. A method as in Claim 16 wherein said vector is a phagemid.

19. A method as in Claim 16 wherein said vector is a cosmid.

20. A method as in Claim 16 wherein said vector is a bacterial phage lambda.

21. A method of synthesizing an antisense proviral molecular clone comprising the steps of:

a) inserting DNA encoding a naturally occurring virus into a vector;

b) creating an antisense fragment in said DNA by carrying out a polymerase chain reaction using a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate as a template, said section of a gene is bordered by a unique restriction enzyme A at its first end and by a unique restriction enzyme site B at its second end, and using

primer 1 comprising DNA complementary to a first end of said section of DNA as its 3' half, and DNA containing said restriction site B as its 5' half, and

primer 2 comprising DNA complementary to a second end of said section of DNA as its 3' half, and DNA containing said restriction site A as its 5' half,

as primers to produce PCR amplification products;

c) digesting said vector with restriction enzyme A and restriction enzyme B to release said section of a gene;

d) digesting said PCR amplification products with restriction enzyme A and restriction enzyme B to release said antisense fragment; and

e) ligating said antisense fragment into said vector,

wherein said antisense fragment enc d s antisense RNA capable of binding and inactivating mRNA encoded by said gene encoding a transactivating protein.

22. A procaryotic or eucaryotic host cell stably transfected with:

a) a first DNA sequence including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding and inactivating mRNA encoded by said gene encoding a transactivating protein; and

b) a second DNA sequence encoding said transactivating protein;

in a manner allowing expression of an antisense virus.

23. A host cell as in claim 22 wherein said second DNA sequence encodes mRNA which does not bind to said antisense RNA.

24. A host cell as in claim 22 wherein said naturally occurring virus is selected from the group consisting of HIV-1, HIV-2 and SIV.

25. A process for the production of an antisense virus, said process comprising:

a) growing under suitable nutrient conditions procaryotic or eucaryotic host cells transfected with:

i) a first DNA sequence including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding and inactivating mRNA encoded by said gene encoding a transactivating protein, and

ii) a second DNA sequence encoding said transactivating protein in a manner allowing expression of said antisense virus, and

b) isolating said antisense virus.

26. A process as in Claim 25 wherein said host cells are transfected with said second DNA sequence prior to being transfected with said first DNA sequence.

27. A method of treating a viral infection comprising administering to an infected animal a therapeutically effective amount of an antisense virus as in Claim 1.

28. A method as in Claim 27 wherein said infected animal is a human, and said section of a gene is from said human.

29. A method of preventing a viral infection comprising administering to an animal a therapeutically effective amount of an antisense virus as in Claim 1.

30. A method as in Claim 28 wherein said naturally occurring virus is selected from the group consisting of HIV-1, HIV-2, and SIV.

31. An antisense-ribozyme virus comprising:

a viral coat sufficiently duplicative of a naturally occurring virus viral coat to allow the infectivity of said naturally occurring virus, and

nucleic acid including an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding and inactivating mRNA encoded by said gene encoding a transactivating protein, said antisense fragment also encoding at least one ribozyme capable of cleaving said mRNA.

32. An antisense-ribozyme virus as in Claim 31 wherein said antisense-ribozyme virus is replication defective.

33. An antisense-ribozyme virus as in Claim 31 wherein said nucleic acid includes all of the structural genes of said naturally occuring virus.

34. An antisense-ribozyme virus as in Claim 31 wherein said nucl ic acid includes all of the regulatory genes of said naturally occurring virus except said gene encoding a transactivating protein.

35. An antisense-ribozyme virus as in Claim 31 wherein except for said antisense fragment which encodes antisense RNA, said antisense-ribozyme virus is the same as said naturally occurring virus.

36. An antisense-ribozyme virus as in Claim 31 wherein said ribozyme is a hammerhead ribozyme.

37. An antisense-ribozyme virus as in Claim 31 wherein said naturally occurring virus is an animal virus.

38. An antisense-ribozyme virus as in Claim 31 wherein said naturally occurring virus is a DNA virus.

39. An antisense-ribozyme virus as in Claim 31 wherein said naturally occurring virus is an RNA virus.

40. An antisense-ribozyme virus as in Claim 39 wherein said naturally occurring virus is a retrovirus.

41. An antisense-ribozyme virus as in Claim 40 wherein said naturally occurring virus is selected from the group consisting of HIV-1, HIV-2 and SIV.

42. An antisense-ribozyme virus as in Claim 41 wherein said antisense fragment which encodes antisense RNA is a section of a gen selected from the group consisting of tat, rev and vpr which has be n turned antisense and which includes at least one ribozyme.

43. An antisense-ribozyme virus as in Claim 41 wherein said mRNA is an mRNA encoded by a gene s lected from the group consisting f tat, rev, and vpr.

44. An antisense-ribozyme proviral molecular clone including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding mRNA encoded by said gene encoding a transactivating protein, said antisense fragment also encoding at least one ribozyme capable of cleaving said mRNA.

45. A method of synthesizing an antisense-ribozyme proviral molecular clone comprising the steps of:

a) inserting DNA encoding a naturally occurring virus into a vector;
b) creating an antisense fragment in said DNA by turning antisense a section of a gene of said DNA, said gene encoding a transactivating protein required for said naturally occurring virus to replicate, and
c) inserting DNA encoding at least one ribozyme in said antisense fragment such that the transcription product of said antisense fragment is antisense RNA capable of binding and cleaving mRNA encoded by said gene encoding a transactivating protein.

46. A method of synthesizing an antisense-ribozyme proviral molecular clone comprising the steps of:

a) inserting DNA encoding a naturally occurring virus into a vector;
b) creating an antisense fragment in said DNA by carrying out a polymerase chain reaction using a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate as a template, said section of a gene is bordered by a unique restriction enzyme A of its first end and by a unique restriction enzyme site B at its second end, and using

primer 1 comprising DNA compl mentary to a first end of said section of DNA as its 3' half, and DNA c ntaining said restriction site B as its 5' half,

primer 2 comprising DNA complementary to a second end of said section of DNA as its 3' half, and DNA containing said restriction site A as its 5' half, and

at least one bridging primer comprising DNA complementary to the 3' side of a ribozyme cleavage site as its 5' third, DNA complementary to the 5' side of said ribozyme cleavage site as its 3' third, and DNA encoding a ribozyme as its middle third,

as primers to produce PCR amplification products;

c) digesting said vector with restriction enzyme A and restriction enzyme B to release said section of a gene;

d) digesting said PCR amplification products with restriction enzyme A and restriction enzyme B to release said antisense fragment; and

e) ligating said antisense fragment into said vector,

wherein said ribozyme cleavage site is selected such that the transcription product of said antisense fragment is antisense RNA capable of binding and cleaving mRNA encoded by said gene encoding a transactivating protein.

47. A procaryotic or eucaryotic host cell stably transfected with:

a) a first DNA sequence including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding mRNA encoded by said gene encoding a transactivating protein, said antisense fragment also encoding at least one ribozyme capable of cleaving said mRNA; and

b) a second DNA sequence encoding said transactivating protein;

in a manner allowing expression of an antisense-ribozyme virus.

48. A host cell as in claim 47 wherein said second DNA sequence encodes mRNA which does not bind to said antisense RNA and which is n t cleaved by said ribozyme.

49. A host cell as in claim 47 wherein said naturally occurring virus is selected from the group consisting of HIV-1, HIV-2, and SIV.

50. A process for the production of an antisense ribozyme virus, said process comprising:

a) growing under suitable nutrient conditions procaryotic or eucaryotic host cells transfected with:

i) a first DNA sequence including structural genes of a naturally occurring virus, and an antisense fragment which is antisense to a section of a gene encoding a transactivating protein required for said naturally occurring virus to replicate, said antisense fragment encoding antisense RNA capable of binding mRNA encoded by said gene encoding a transactivating protein, said antisense fragment also encoding at least one ribozyme capable of cleaving said mRNA, and

ii) a second DNA sequence encoding said transactivating protein, in a manner allowing expression of said antisense ribozyme virus, and

b) isolating said antisense ribozyme virus.

51. A process as in Claim 50 wherein said host cells are transfected with said second DNA sequence prior to being transfected with said first DNA sequence.

52. A method of treating a viral infection comprising administering to an infected animal a therapeutically effective amount of an antisense-ribozyme virus as in Claim 31.

53. A method as in Claim 52 wherein said infected animal is a human and said section of a gene is from said human.

54. A method of preventing a viral infection c mprising administering to an animal a therapeutically effective amount of an antisense-ribozyme virus as in Claim 31.

55. A method as in Claim 53 wherein said naturally occurring virus is selected from the group consisting of HIV-1, HIV-2, and SIV.

56. A method of connecting a first DNA segment to a second DNA segment, said first DNA segment and said second DNA segment being separated by a length of DNA, or located on different molecules, comprising the steps of:

carrying out polymerase chain reaction using said DNA segments as templates, and using

a primer A complementary to the 5' end of said first DNA segment,

a primer B complementary to the 3' end of said second DNA segment, and

a bridging primer comprising DNA complementary to the 3' end f said first DNA segment as its 5' half, and DNA complementary to the 5' end of said second DNA segment as its 3' half,

as primers.

57. A method as in Claim 56, wherein the molar concentration of primers A and B are the same, and the molar concentration of said bridging primer is about 1/10 of the molar concentration of primer A or B.

58. A method of synthesizing a DNA sequence comprising the steps of:

a) synthesizing a series of oligodeoxynucleotides including:

a first oligodeoxynucleotide having a 5' end complementary to the 5' end of said DNA sequence and a 3' end complementary to the 5' end of one other oligodeoxynucleotide,

internal oligodeoxynucleotides wherein the 3' end of each oligodeoxynucleotide is complementary to the 5' end of one other oligodeoxynucleotide, and

a last olig deoxynucleotide having a 3' end compl mentary to the 3' end of said DNA s quence and a 5' end complementary to the 3' end of one other oligodeoxynucleotide,

wherein said series extends the full length of said DNA sequence to be synthesized;

b) carrying out a thermal cycling connection-amplification reaction on a thermal cycler under reaction conditions suitable for thermal stable DNA polymerase in the presence of:

i) said oligodeoxynucleotides;

ii) four 2'-deoxynucleoside 5'-triphosphatase; and

iii) thermal stable polymerase.

59. A method as in claim 58 wherein said first and said last oligodeoxynucleotides are added in equal amounts, and each internal oligodeoxynucleotide is added at about 1/10 that of said first or said last oligodeoxynucleotide.

60. A method as in Claim 58 wherein said DNA sequence is a regulatory gene sequence.

61. A method as in Claim 60 wherein said DNA sequence is a protein coding sequence.

62. A method as in Claim 61 wherein said DNA sequence is a protein coding sequence of a viral gene.

63. A method as in Claim 62 wherein said DNA sequence is a protein coding sequence of a viral gene with a diversified nucleotide sequence.

64. A nucleic acid selected from the group consisting of SEQ ID NO:1-38.

INTERNATIONAL SEARCH REPORT

International application No.
PCT/US93/07179

A. CLASSIFICATION OF SUBJECT MATTER

IPC(5) :Please See Extra Sheet.
US CL :424/89, 93; 435/320.1, 69.1, 172.1, 91, 235.1, 240.2, 252.3
According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 424/89, 93; 435/320.1, 69.1, 172.1, 91, 235.1, 240.2, 252.3

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, Dialog, Medline, biosis, biotech
Search Terms: Antisense virus, ribozyme virus, recombinant

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	Proceedings of the National Academy of Sciences, Vol. 88, issued May 1991, L. Han et al., "Inhibition of Moloney Murine Leukemia Virus-Induced Leukemia in Transgenic Mice Expressing Antisense RNA Complementary to the Retroviral Packaging Sequences", pages 4313-4317, see page 4314.	1-64
A	Science, Vol. 253, issued 02 August 1991, Szczylik et al., "Selective Inhibition of Leukemia Cell Proliferation by BCR-ABL Antisnese Oligodeoxynucleotides", pages 562-565, see whole document.	1-64

[X] Further documents are listed in the continuation of Box C. [ ] See patent family annex.

*	Special categories of cited documents:	"T"	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
"A"	document defining the general state of the art which is not considered to be part of particular relevance	"X"	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
"E"	earlier document published on or after the international filing date	"Y"	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
"L"	document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	"&"	document member of the same patent family
"O"	document referring to an oral disclosure, use, exhibition or other means		
"P"	document published prior to the international filing date but later than the priority date claimed
